**Abstract.** Pairings on the Jacobians of (hyper-)elliptic curves have received considerable attention not only as a tool to attack curve based cryptosystems but also as a building block for constructing cryptographic schemes with new and novel properties. Motivated by the work of Scott [34], we investigate how to use efficiently computable automorphisms to speed up pairing computations on two families of non-supersingular genus 2 hyperelliptic curves over prime fields. Our findings lead to new variants of Miller’s algorithm in which the length of the main loop can be up to 4 times shorter than that of the original Miller’s algorithm in the best case. We also implement the calculation of the Tate pairing on both a supersingular and a non-supersingular genus 2 curve with the same embedding degree of  $k = 4$ . Combining the new algorithm with known optimization techniques, we show that pairing computations on non-supersingular genus 2 curves over prime fields use up to 56.2% fewer field operations and run about 10% faster than supersingular genus 2 curves for the same security level.

**Keywords:** Genus 2 non-supersingular hyperelliptic curves, Tate pairing, Miller’s algorithm, Automorphism, Efficient implementation.

## 1 Introduction

Pairing based cryptography is a relatively new area of cryptography centered around particular functions with interesting properties. Initially, bilinear pairings were introduced to cryptography for attacking instances of the discrete logarithm problem (DLP) on elliptic curves and hyperelliptic curves [14, 28]. With the advent of non-interactive key distribution [33], tripartite key exchange [24], and identity based encryption [5], the design of pairing based cryptographic protocols has received a lot of attention from the research community. The implementation of pairing based protocols requires the efficient computation of pairings. To date, the Weil and Tate pairings and their variants such as the Eta and Ate pairings on Jacobians of (hyper-)elliptic curves are the only efficient instantiations of cryptographically useful bilinear maps.

There has been a lot of work on efficient implementation of pairings on elliptic curves, and many important techniques have been proposed to accelerate the computation of the Tate pairing and its variants on elliptic curves [2–4, 22]. Furthermore, the subject of pairing computations on hyperelliptic curves is also receiving an increasing amount of attention. Choie and Lee [6] investigated the implementation of the Tate pairing on supersingular genus 2 hyperelliptic curves over prime fields. Later on, Ó hÉigearthaigh and Scott [21] improved the implementation of [6] significantly by using a new variant of Miller’s algorithm combined with various optimization techniques. Duursma and Lee [10] presented a closed formula for the Tate pairing computation on a very special family of supersingular hyperelliptic curves. Barreto *et. al.* [2] generalized the results of Duursma and Lee and proposed the Eta pairing approach for efficiently computing the Tate pairing on supersingular

genus 2 curves over binary fields. In particular, their algorithm leads to the fastest pairing implementation in the literature. In [27], Lee *et. al.* considered the Eta pairing computation on general divisors on supersingular genus 3 hyperelliptic curves with the form of  $y^2 = x^7 - x \pm 1$ . Recently, the Ate pairing, originally defined for elliptic curves, has been generalized to hyperelliptic curves [18] as well. Although the Eta and Ate pairings hold the record for speed at the present time, we will focus our attention on the Tate pairing in this paper. The main reason is that the Tate pairing is uniformly available across a wide range of hyperelliptic curves and subgroups, whereas the Eta pairing is only defined for supersingular curves and the Ate pairing incurs a huge performance penalty in the context of ordinary genus 2 curves ([18, Table 6]).

Motivated by previous work in [34, 38, 39], we consider pairing computations on two families of non-supersingular genus 2 hyperelliptic curves over prime fields. We first explicitly give efficiently computable automorphisms (also isogenies) and the dual isogenies on the divisor class group of these curves. We then exploit the automorphism in lieu of the order of the torsion group to construct the rational functions required in Miller's algorithm, and shorten the length of the main loop in Miller's algorithm as a result. Based on the new construction of the rational functions, we propose new variants of Miller's algorithm for computing the Tate pairing on certain non-supersingular genus 2 curves over prime fields. In the best case, the length of the loop in our new variant can be up to 4 times shorter than that of the original Miller's algorithm. Furthermore, we generate a non-supersingular pairing-friendly genus 2 curve with embedding degree 4 and compare the performance of our new algorithm with that of the variant proposed by Ó hÉigartaigh and Scott [21] for supersingular genus 2 curves. Theoretical analysis shows that our new algorithm uses 56.2% fewer field operations than that of [21] for the same security level. However, the size of the field where the non-supersingular curve is defined is 1.285 times larger than that of the field used for supersingular curves, which somewhat offsets these gains. Nevertheless, our experimental results show that using the non-supersingular genus 2 curve one can still obtain a 10% performance improvement over the supersingular curve.

The rest of this paper is organized as follows. Section 2 gives a short introduction to the Tate pairing on hyperelliptic curves and Miller's algorithm for computing the pairing. In Section 3 we recall supersingular genus 2 curves over prime fields which have been used for pairing computations, and introduce two families of non-supersingular genus 2 curves with efficiently computable automorphisms. In Section 4 we prove the main results of our contribution and propose new variants of Miller's algorithm. Section 5 details the various techniques for efficiently implementing the Tate pairing on a non-supersingular genus 2 curve with embedding degree 4, analyzes the computational cost of our new algorithm and gives experimental results. Finally, Section 6 concludes this paper.

## 2 Mathematical Background

In this section, we present a brief introduction to the definition of the Tate pairing on hyperelliptic curves and also review Miller's algorithm for computing pairings. For more details, the reader is referred to [1].

### 2.1 Tate Pairing on Hyperelliptic Curves

Let  $\mathbb{F}_q$  be a finite field with  $q$  elements, and  $\overline{\mathbb{F}}_q$  be its algebraic closure. Let  $C$  be a hyperelliptic curve of genus  $g$  over  $\mathbb{F}_q$ , and let  $\mathcal{J}_C$  denote the degree zero divisor class group of  $C$ . We say that a subgroup of the divisor class group  $\mathcal{J}_C(\mathbb{F}_q)$  has *embedding degree*  $k$  if the order  $n$  of the subgroup divides  $q^k - 1$ , but does not divide  $q^i - 1$  for any  $0 < i < k$ . For our purpose,  $n$  should be a (large) prime with  $n \mid \#\mathcal{J}_C(\mathbb{F}_q)$  and  $\gcd(n, q) = 1$ . Let  $\mathcal{J}_C(\mathbb{F}_{q^k})[n]$  be the  $n$ -torsion group and  $\mathcal{J}_C(\mathbb{F}_{q^k})/n\mathcal{J}_C(\mathbb{F}_{q^k})$  be the quotient group. Then the Tate pairing is a well defined, non-degenerate, bilinear map [14]:

$$\langle \cdot, \cdot \rangle_n : \mathcal{J}_C(\mathbb{F}_{q^k})[n] \times \mathcal{J}_C(\mathbb{F}_{q^k})/n\mathcal{J}_C(\mathbb{F}_{q^k}) \rightarrow \mathbb{F}_{q^k}^* / (\mathbb{F}_{q^k}^*)^n,$$

defined as follows: let  $D_1 \in \mathcal{J}_C(\mathbb{F}_{q^k})[n]$ , with  $\text{div}(f_{n,D_1}) = nD_1$  for some rational function  $f_{n,D_1} \in \mathbb{F}_{q^k}(C)^*$ . Let  $D_2 \in \mathcal{J}_C(\mathbb{F}_{q^k})/n\mathcal{J}_C(\mathbb{F}_{q^k})$  with  $\text{supp}(D_1) \cap \text{supp}(D_2) = \emptyset$  (to ensure a non-trivial pairing value). The Tate pairing of two divisor classes  $\overline{D}_1$  and  $\overline{D}_2$  is then defined as

$$\langle \overline{D}_1, \overline{D}_2 \rangle_n = f_{n,D_1}(D_2) = \prod_{P \in C(\mathbb{F}_q)} f_{n,D_1}(P)^{\text{ord}_P(D_2)}.$$

Note that the Tate pairing as detailed above is only defined up to  $n$ -th powers. One can show that if the function  $f_{n,D_1}$  is properly normalized, we only need to evaluate the rational function  $f_{n,D_1}$  at the effective part of the reduced divisor  $D_2$  in order to compute the Tate pairing [18].

In practice, the fact that the Tate pairing is only defined up to  $n$ -th power is usually undesirable, and many pairing-based protocols require a unique pairing value. Hence one defines the *reduced* pairing as

$$\langle \overline{D}_1, \overline{D}_2 \rangle_n^{(q^k-1)/n} = f_{n,D_1}(D_2)^{(q^k-1)/n} \in \mu_n \subset \mathbb{F}_{q^k}^*,$$

where  $\mu_n = \{u \in \mathbb{F}_{q^k}^* \mid u^n = 1\}$  is the group of  $n$ -th roots of unity. In the rest of this paper we will refer to the extra powering required to compute the reduced pairing as the *final exponentiation*. One of the important properties of the reduced pairing we will use in this paper is that for any positive integer  $N$  satisfying  $n \mid N$  and  $N \mid q^k - 1$  we have

$$\langle D_1, D_2 \rangle_n^{(q^k-1)/n} = \langle D_1, D_2 \rangle_N^{(q^k-1)/N}. \quad (1)$$

## 2.2 Miller's Algorithm

The main task involved in the computation of the Tate pairing  $\langle \overline{D}_1, \overline{D}_2 \rangle_n$  is to construct a rational function  $f_{n,D_1}$  such that  $\text{div}(f_{n,D_1}) = nD_1$ . In [29] (see also [30]), Miller described a polynomial time algorithm, known universally as Miller's algorithm, to construct the function  $f_{n,D_1}$  and compute the Weil pairing on elliptic curves. However, the algorithm can be easily adapted to compute the Tate pairing on hyperelliptic curves.

Let  $G_{iD_1, jD_1} \in \mathbb{F}_{q^k}(C)^*$  be a rational function with  $\text{div}(G_{iD_1, jD_1}) = iD_1 + jD_1 - (iD_1 \oplus jD_1)$  where  $\oplus$  is the group law on  $\mathcal{J}_C$  and  $(iD_1 \oplus jD_1)$  is reduced. Miller's algorithm constructs the rational function  $f_{n,D_1}$  based on the following iterative formula:

$$f_{i+j, D_1} = f_{i, D_1} f_{j, D_1} G_{iD_1, jD_1}.$$

Algorithm 1 shows the basic version of Miller's algorithm for computing the reduced Tate pairing on hyperelliptic curves according to the above iterative relation. A more detailed version of Miller's algorithm for hyperelliptic curves can be found in [18].

---

### Algorithm 1 Miller's Algorithm for Hyperelliptic Curves (basic version)

---

IN:  $\overline{D}_1 \in \mathcal{J}_C(\mathbb{F}_{q^k})[n], \overline{D}_2 \in \mathcal{J}_C(\mathbb{F}_{q^k})$ , represented by  $D_1$  and  $D_2$  with  $\text{supp}(D_1) \cap \text{supp}(D_2) = \emptyset$

OUT:  $\langle D_1, D_2 \rangle_n^{(q^k-1)/n}$

1.  $f \leftarrow 1, T \leftarrow D_1$

2. **for**  $i \leftarrow \lfloor \log_2(n) \rfloor - 1$  **downto** 0 **do**

3.      $\triangleright$  Compute  $T'$  and  $G_{T, T}(x, y)$  such that  $T' = 2T - \text{div}(G_{T, T})$

4.      $f \leftarrow f^2 \cdot G_{T, T}(D_2), \overline{T} \leftarrow [2]\overline{T}$

5. **if**  $n_i = 1$  **then**

6.      $\triangleright$  Compute  $T'$  and  $G_{T, D_1}(x, y)$  such that  $T' = T + D_1 - \text{div}(G_{T, D_1})$

7.      $f \leftarrow f \cdot G_{T, D_1}(D_2), \overline{T} \leftarrow \overline{T} \oplus \overline{D}_1$

8. **Return**  $f^{(q^k-1)/n}$

---

Choi and Lee [6] described how to explicitly find the rational function  $G(x, y)$  in the above algorithm 1 for the case of genus 2 hyperelliptic curves. Their results can be summarized as follows: Let  $D_1 = [u_1, v_1]$  and  $D_2 = [u_2, v_2]$  be the two reduced divisors in  $\mathcal{J}_C(\mathbb{F}_{q^k})$  that are being added. In the composition stage of Cantor's algorithm, we compute the polynomial  $\delta(x)$  which is the greatest common divisor of  $u_1, u_2$  and  $v_1 + v_2$  and a divisor  $D'_3 = [u'_3, v'_3]$ , which is in the same divisor class as  $D_3 = [u_3, v_3] = \overline{D_1} + \overline{D_2}$ . At this point, two cases may occur:

1. If the divisor  $D'_3$  is already reduced following the composition stage, then the rational function  $G(x, y) = \delta(x)$ .
2. If this is not the case, then the rational function  $G(x, y) = \delta(x) \cdot \frac{y - v'_3(x)}{u_3(x)}$ .

In the most frequent cases<sup>3</sup>  $\delta = 1$  and thus  $G(x, y) = \frac{y - v'_3(x)}{u_3(x)}$ .

### 3 Supersingular Curves and Non-supersingular Curves

In this section, we first recall supersingular genus 2 curves over  $\mathbb{F}_p$  which have been used to implement the Tate pairing. Then, by making a small change to the definition of these curves, we produce two families of non-supersingular genus 2 curves over  $\mathbb{F}_p$  with efficiently computable automorphisms which provide potential advantages for pairing computations.

#### 3.1 Supersingular Genus 2 Curves over $\mathbb{F}_p$

Theoretically, supersingular genus 2 hyperelliptic curves exist over  $\mathbb{F}_p$  with an embedding degree of  $k = 6$  [32]. However, only supersingular genus 2 curves with an embedding degree of  $k = 4$  are known to the cryptographic community at the present time [7]. In [6, 21], the authors investigated the efficient implementation of the Tate pairing on supersingular genus 2 curves with embedding degree 4. The curve used in their implementation is defined by the following equation:

$$C_1 : y^2 = x^5 + a, \quad a \in \mathbb{F}_p^* \text{ and } p \equiv 2, 3 \pmod{5}.$$

On these supersingular curves a *modified pairing*  $\langle D_1, \psi(D_1) \rangle_n^{(p^k-1)/n}$  is computed, where the map  $\psi_1(\cdot)$  is a *distortion map* that maps elements in  $C_1(\mathbb{F}_p)$  to  $C_1(\mathbb{F}_{p^4})$ . The distortion map  $\psi_1$  is given as  $\psi_1(x, y) = (\xi_5 x, y)$ , where  $\xi_5$  is a primitive 5-th root of unity in  $\mathbb{F}_{p^4}$ . We also note that another family of supersingular genus 2 curves over  $\mathbb{F}_p$  with embedding degree 4 [7] is also suitable for implementing pairings. Such curves are given by an equation of the form

$$C_2 : y^2 = x^5 + ax, \quad a \in \mathbb{F}_p^* \cap \overline{QR}_p \text{ and } p \equiv 5 \pmod{8},$$

where  $\overline{QR}_p$  denotes the set of quadratic non-residues modulo  $p$ . The distortion map for the curve  $C_2$  is defined as  $\psi_2(x, y) = (\xi_8^2 x, \xi_8 y)$ , where  $\xi_8$  is a primitive 8-th root of unity in  $\mathbb{F}_{p^4}$ .

#### 3.2 Non-Supersingular Genus 2 Curves over $\mathbb{F}_p$

Motivated by the work in [34, 38, 39], we consider now the following two families of non-supersingular genus 2 hyperelliptic curves over  $\mathbb{F}_p$ :

$$\begin{aligned} C'_1 : y^2 &= x^5 + a, \quad a \in \mathbb{F}_p^* \text{ and } p \equiv 1 \pmod{5}, \\ C'_2 : y^2 &= x^5 + ax, \quad a \in \mathbb{F}_p^* \text{ and } p \equiv 1 \pmod{8}. \end{aligned}$$

<sup>3</sup> For addition, the inputs are two co-prime polynomials of degree 2, and for doubling the input is a square free polynomial of degree 2.

Curves of this form exist which are pairing friendly (see Section 4). Note that the only difference between the curves  $C_i$  and  $C'_i$  ( $i = 1, 2$ ) is the congruence condition applied to the characteristic  $p$ . Although distortion maps do not exist on these non-supersingular curves, both  $C'_1$  and  $C'_2$  have efficiently-computable *endomorphisms*. In fact, these endomorphisms also induce efficient *automorphisms* on the divisor class groups of  $C'_1$  and  $C'_2$ , which have been used to accelerate the scalar multiplication for hyperelliptic curve cryptosystems [31] and to attack the discrete log problems on the Jacobians [9, 17]. In the next section, we will show how to speed up the computation of the Tate pairing using these efficiently computable automorphisms on the curves  $C'_1$  and  $C'_2$ . We first recall some basic facts which will be used in this work.

For the curve  $C'_1$ , the morphism  $\psi_1$  defined by  $P = (x, y) \mapsto \psi_1(P) = (\xi_5 x, y)$  (see Section 3.1 and notice  $\xi_5 \in \mathbb{F}_p$  now) induces an efficient non-trivial automorphism of order 5 on the divisor class group  $\mathcal{J}_{C'_1}(\mathbb{F}_p)$ . The formulae for  $\psi_1$  on the Jacobian are given by

$$\begin{aligned} \psi_1 : [x^2 + u_1x + u_0, v_1x + v_0] &\mapsto [x^2 + \xi_5 u_1x + \xi_5^2 u_0, \xi_5^{-1} v_1x + v_0] \\ [x + u_0, v_0] &\mapsto [x + \xi_5 u_0, v_0] \\ \mathcal{O} &\mapsto \mathcal{O}. \end{aligned}$$

The characteristic polynomial of  $\psi_1$  is given by  $P(t) = t^4 + t^3 + t^2 + t + 1$ . Since the automorphism  $\psi_1$  is also an *isogeny*, we can construct its *dual isogeny* as follows:

$$\begin{aligned} \widehat{\psi}_1 : [x^2 + u_1x + u_0, v_1x + v_0] &\mapsto [x^2 + \xi_5^{-1} u_1x + \xi_5^{-2} u_0, \xi_5 v_1x + v_0] \\ [x + u_0, v_0] &\mapsto [x + \xi_5^{-1} u_0, v_0] \\ \mathcal{O} &\mapsto \mathcal{O}. \end{aligned}$$

Note that  $\psi_1 \circ \widehat{\psi}_1 = [1]$  and  $\# \text{Ker } \psi_1 = \text{deg}[1] = 1$ , and  $\widehat{\psi}_1$  is also a non-trivial automorphism on the curve  $C'_1$ .

Let  $D \in \mathcal{J}_{C'_1}(\mathbb{F}_p)$  be a reduced divisor of a large prime order  $n$ . From [31], we know that the automorphisms  $\psi_1$  and  $\widehat{\psi}_1$  act respectively as multiplication maps by  $[\lambda_1]$  and  $[\widehat{\lambda}_1]$  on the subgroup  $\langle D \rangle$  of  $\mathcal{J}_{C'_1}(\mathbb{F}_p)$ , where  $\lambda_1$  and  $\widehat{\lambda}_1$  are the two roots of the equation  $t^4 + t^3 + t^2 + t + 1 \equiv 0 \pmod{n}$ . Furthermore, it is easily seen that  $[\lambda_1]D = \psi_1(D)$  can be obtained with only three or one field multiplications in  $\mathbb{F}_p$  for a *general divisor* and a *degenerate divisor*, respectively. In the genus 2 context, a general divisor has two finite points in the support, whereas a degenerate divisor has only a single finite point in its support.

Similarly, for the curve  $C'_2$ , the morphism  $\psi_2$  defined by  $P = (x, y) \mapsto \psi_2(P) = (\xi_8^2 x, \xi_8 y)$  (see Section 3.1 and notice  $\xi_8 \in \mathbb{F}_p$  now) induces an efficient non-trivial automorphism of order 8 on the divisor class group  $\mathcal{J}_{C'_2}(\mathbb{F}_p)$  as follows.

$$\begin{aligned} \psi_2 : [x^2 + u_1x + u_0, v_1x + v_0] &\mapsto [x^2 + \xi_8^2 u_1x + \xi_8^4 u_0, \xi_8^{-1} v_1x + \xi_8 v_0] \\ [x + u_0, v_0] &\mapsto [x + \xi_8^2 u_0, \xi_8 v_0] \\ \mathcal{O} &\mapsto \mathcal{O}. \end{aligned}$$

The characteristic polynomial of  $\psi_2$  is given by  $P(t) = t^4 + 1$  and the dual isogeny of  $\psi_2$  is defined as follows

$$\begin{aligned} \widehat{\psi}_2 : [x^2 + u_1x + u_0, v_1x + v_0] &\mapsto [x^2 + \xi_8^{-2} u_1x + \xi_8^4 u_0, \xi_8 v_1x + \xi_8^{-1} v_0] \\ [x + u_0, v_0] &\mapsto [x + \xi_8^{-2} u_0, \xi_8^{-1} v_0] \\ \mathcal{O} &\mapsto \mathcal{O}. \end{aligned}$$

It is not difficult to show that  $\psi_2 \circ \widehat{\psi}_2 = [1]$  and  $\# \text{Ker } \psi_2 = \text{deg}[1] = 1$ , and  $\widehat{\psi}_2$  is also a non-trivial automorphism on the curve  $C'_2$ . Let  $D \in \mathcal{J}_{C'_2}(\mathbb{F}_p)$  be a reduced divisor of a large prime order  $n$ . Then the automorphism  $\psi_2$  acts as a multiplication map by  $\lambda_2$  on the subgroup  $\langle D \rangle$  of  $\mathcal{J}_{C'_2}(\mathbb{F}_p)$ , where  $\lambda_2$  is a root of the equation  $t^4 + 1 \equiv 0 \pmod{n}$ . Moreover,  $[\lambda_2]D = \psi_2(D)$  can be computed with four or two field multiplications in  $\mathbb{F}_p$  for a general divisor and a degenerate divisor, respectively.

## 4 Efficient Pairings on Non-supersingular Genus 2 Curves

In this section we investigate efficient algorithms for computing the Tate pairing on the two families of genus 2 hyperelliptic curves  $C'_1$  and  $C'_2$  defined in Section 3.2. We show how to use the efficiently-computable automorphisms on these curves to shorten the length of the loop in Miller's algorithm. As a result, we propose new variants of Miller's algorithm for certain non-supersingular genus 2 curves over large prime fields.

### 4.1 Pairing Computation with Efficient Automorphisms

In this subsection, we present the main results of this paper in the following theorems and show their correctness. The pairing computation on the curve  $C'_1$  is first examined.

**Theorem 1.** *Let  $C'_1$  be a non-supersingular genus 2 hyperelliptic curve over  $\mathbb{F}_p$  as above, with embedding degree  $k > 1$  and automorphisms  $\psi_1$  and  $\widehat{\psi}_1$  defined as above. Let  $D_1 = [u_1(x), v_1(x)] \in \mathcal{J}_{C'_1}(\mathbb{F}_p)$  be a reduced divisor of prime order  $n$ , where  $n^2 \nmid \#\mathcal{J}_{C'_1}(\mathbb{F}_p)$ . Let  $[\lambda_1]$  act as the multiplication map on the subgroup  $\langle D_1 \rangle$  defined as above such that  $[\lambda_1]D_1 = \psi_1(D_1)$ . Suppose  $m \in \mathbb{Z}$  is such that  $mn = \lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1 + 1$ . Let rational functions  $\frac{c_1(x,y)}{d_1(x,y)}, \frac{c_2(x,y)}{d_2(x,y)}, \frac{c_3(x,y)}{d_3(x,y)} \in \mathbb{F}_p(C'_1)^*$  respectively satisfy the following three relations:*

$$\begin{aligned} [\lambda_1]D_1 + [\lambda_1^2]D_1 - ([\lambda_1]D_1 \oplus [\lambda_1^2]D_1) &= \operatorname{div} \left( \frac{c_1(x,y)}{d_1(x,y)} \right), \\ [\lambda_1^3]D_1 + [\lambda_1^4]D_1 - ([\lambda_1^3]D_1 \oplus [\lambda_1^4]D_1) &= \operatorname{div} \left( \frac{c_2(x,y)}{d_2(x,y)} \right), \\ [\lambda_1 + \lambda_1^2]D_1 + [\lambda_1^3 + \lambda_1^4]D_1 - ([\lambda_1 + \lambda_1^2]D_1 \oplus [\lambda_1^3 + \lambda_1^4]D_1) &= \operatorname{div} \left( \frac{c_3(x,y)}{d_3(x,y)} \right). \end{aligned}$$

Let  $g(x,y) = \frac{c_1(x,y) \cdot c_2(x,y) \cdot c_3(x,y)}{d_1(x,y) \cdot d_2(x,y)}$ . Then for  $D_2 \in \mathcal{J}_{C'_1}(\mathbb{F}_{p^k})$ , we have

$$\langle D_1, D_2 \rangle_n^{\frac{m(p^k-1)}{n}} = \left[ f_{\lambda_1^3 + \lambda_1^2 + \lambda_1 + 1, D_1}^{\lambda_1^2 + \lambda_1 + 1}(D_2) \cdot f_{\lambda_1, D_1}^{\lambda_1 + 1}(\widehat{\psi}_1(D_2)) \cdot f_{\lambda_1, D_1}^{\lambda_1 + 1}(\psi_1^2(D_2)) \cdot f_{\lambda_1, D_1}(\psi_1^2(D_2)) \cdot g(D_2) \right]^{\frac{p^k-1}{n}}.$$

Note that the condition that  $\lambda_1$  satisfies  $\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1 + 1 \equiv 0 \pmod{n}$  guarantees the existence of the integer  $m$ . Furthermore, the pairing value  $\langle D_1, D_2 \rangle_n^{\frac{m(p^k-1)}{n}}$  will be non-degenerate if  $n \nmid m$  and  $\operatorname{supp}(D_1) \cap \operatorname{supp}(D_2) = \emptyset$ . We split the proof of the Theorem 1 into the following lemmas.

**Lemma 1.** *With the notation as above, we have*

$$\langle D_1, D_2 \rangle_n^{\frac{m(p^k-1)}{n}} = \left( f_{\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1 + 1, D_1}(D_2) \cdot u_1(D_2) \right)^{\frac{p^k-1}{n}}.$$

*Proof.* From the important property of the reduced pairing (see equation (1)), we have

$$\langle D_1, D_2 \rangle_n^{\frac{m(p^k-1)}{n}} = \langle D_1, D_2 \rangle_{mn}^{\frac{p^k-1}{n}} = f_{mn, D_1}(D_2)^{\frac{p^k-1}{n}}.$$

From the condition that  $mn = \lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1 + 1$ , we get

$$\langle D_1, D_2 \rangle_n^{\frac{m(p^k-1)}{n}} = f_{mn, D_1}(D_2)^{\frac{p^k-1}{n}} = f_{\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1 + 1, D_1}(D_2)^{\frac{p^k-1}{n}}.$$

Since  $[\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1]D_1 = -D_1$ , we obtain the following relation

$$D_1 + [\lambda_1 + \lambda_1^2 + \lambda_1^3 + \lambda_1^4]D_1 = D_1 + (-D_1) = \operatorname{div}(u_1(x)).$$

Therefore, we have

$$\begin{aligned}
 \operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1 + 1, D_1} \right) &= (\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1) D_1 + D_1 \\
 &= \operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1, D_1} \right) + D_1 + [\lambda_1 + \lambda_1^2 + \lambda_1^3 + \lambda_1^4] D_1 \\
 &= \operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1, D_1} \cdot u_1(x) \right),
 \end{aligned}$$

which proves the result.

The next lemma shows the relation between the divisor  $\operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1, D_1} \cdot u_1(x) \right)$  and the divisors  $\operatorname{div} \left( f_{\lambda_1, [\lambda_1^i] D_1} \right)$  for  $i = 0, 1, 2$ , and  $3$ .

**Lemma 2.** *With the notation as above, we have*

$$\operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1, D_1} \cdot u_1(x) \right) = \operatorname{div} \left( f_{\lambda_1, D_1}^{\lambda_1^3 + \lambda_1^2 + \lambda_1 + 1} \cdot f_{\lambda_1, [\lambda_1] D_1}^{\lambda_1^2 + \lambda_1 + 1} \cdot f_{\lambda_1, [\lambda_1^2] D_1}^{\lambda_1 + 1} \cdot f_{\lambda_1, [\lambda_1^3] D_1} \cdot g(x, y) \right).$$

*Proof.* We first note the following relation

$$\begin{aligned}
 \operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1, D_1} \right) &= (\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1) D_1 - [\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1] D_1 \\
 &= \operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3, D_1} \right) + \operatorname{div} \left( f_{\lambda_1^2 + \lambda_1, D_1} \right) + [\lambda_1 + \lambda_1^2] D_1 + [\lambda_1^3 + \lambda_1^4] D_1 - ([\lambda_1 + \lambda_1^2] D_1 \oplus [\lambda_1^3 + \lambda_1^4] D_1) \\
 &= \operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3, D_1} \right) + \operatorname{div} \left( f_{\lambda_1^2 + \lambda_1, D_1} \right) + \operatorname{div} \left( \frac{c_3(x, y)}{d_3(x, y)} \right) \\
 &= \operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3, D_1} \cdot f_{\lambda_1^2 + \lambda_1, D_1} \cdot \frac{c_3(x, y)}{d_3(x, y)} \right)
 \end{aligned}$$

Since  $[\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1] D_1 = -D_1$ , we get  $d_3(x, y) = u_1(x)$ . Therefore, we have

$$\operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1, D_1} \cdot u_1(x) \right) = \operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3, D_1} \cdot f_{\lambda_1^2 + \lambda_1, D_1} \cdot c_3(x, y) \right). \quad (2)$$

Similarly, we can obtain the following two equalities

$$\begin{aligned}
 \operatorname{div} \left( f_{\lambda_1^4 + \lambda_1^3, D_1} \right) &= (\lambda_1^4 + \lambda_1^3) D_1 - [\lambda_1^4 + \lambda_1^3] D_1 \\
 &= \operatorname{div} \left( f_{\lambda_1^4, D_1} \right) + \operatorname{div} \left( f_{\lambda_1^3, D_1} \right) + [\lambda_1^4] D_1 + [\lambda_1^3] D_1 - ([\lambda_1^3] D_1 \oplus [\lambda_1^4] D_1) \\
 &= \operatorname{div} \left( f_{\lambda_1^4, D_1} \right) + \operatorname{div} \left( f_{\lambda_1^3, D_1} \right) + \operatorname{div} \left( \frac{c_2(x, y)}{d_2(x, y)} \right) \\
 &= \operatorname{div} \left( f_{\lambda_1^4, D_1} \cdot f_{\lambda_1^3, D_1} \cdot \frac{c_2(x, y)}{d_2(x, y)} \right)
 \end{aligned} \quad (3)$$

and

$$\begin{aligned}
 \operatorname{div} \left( f_{\lambda_1^2 + \lambda_1, D_1} \right) &= (\lambda_1^2 + \lambda_1) D_1 - [\lambda_1^2 + \lambda_1] D_1 \\
 &= \operatorname{div} \left( f_{\lambda_1^2, D_1} \right) + \operatorname{div} \left( f_{\lambda_1, D_1} \right) + [\lambda_1^2] D_1 + [\lambda_1] D_1 - ([\lambda_1] D_1 \oplus [\lambda_1^2] D_1) \\
 &= \operatorname{div} \left( f_{\lambda_1^2, D_1} \right) + \operatorname{div} \left( f_{\lambda_1, D_1} \right) + \operatorname{div} \left( \frac{c_1(x, y)}{d_1(x, y)} \right) \\
 &= \operatorname{div} \left( f_{\lambda_1^2, D_1} \cdot f_{\lambda_1, D_1} \cdot \frac{c_1(x, y)}{d_1(x, y)} \right)
 \end{aligned} \quad (4)$$

Some easy calculations (see Lemma 2 in [2]) give us

$$\operatorname{div} \left( f_{\lambda_1^4, D_1} \right) = \operatorname{div} \left( f_{\lambda_1, D_1}^{\lambda_1^3} \cdot f_{\lambda_1, [\lambda_1] D_1}^{\lambda_1^2} \cdot f_{\lambda_1, [\lambda_1^2] D_1}^{\lambda_1} \cdot f_{\lambda_1, [\lambda_1^3] D_1} \right) \quad (5)$$

$$\operatorname{div} \left( f_{\lambda_1^3, D_1} \right) = \operatorname{div} \left( f_{\lambda_1, D_1}^{\lambda_1^2} \cdot f_{\lambda_1, [\lambda_1] D_1}^{\lambda_1} \cdot f_{\lambda_1, [\lambda_1^2] D_1} \right) \quad (6)$$

$$\operatorname{div} \left( f_{\lambda_1^2, D_1} \right) = \operatorname{div} \left( f_{\lambda_1, D_1}^{\lambda_1} \cdot f_{\lambda_1, [\lambda_1] D_1} \right) \quad (7)$$

Combining the equations (2)–(7) proves the result.

The following lemma shows how to evaluate functions  $f_{\lambda_1, [\lambda_1^i] D_1}$  ( $i = 1, 2, 3$ ) at the image divisor  $D_2$  by using the function  $f_{\lambda_1, D_1}$ .

**Lemma 3.** *With the notation as above, we have (up to a scalar multiple in  $\mathbb{F}_p^*$ )*

$$\begin{aligned} f_{\lambda_1, [\lambda_1] D_1}(D_2) &= f_{\lambda_1, D_1}(\widehat{\psi}_1(D_2)), \\ f_{\lambda_1, [\lambda_1^2] D_1}(D_2) &= f_{\lambda_1, D_1}(\widehat{\psi}_1^2(D_2)), \\ f_{\lambda_1, [\lambda_1^3] D_1}(D_2) &= f_{\lambda_1, D_1}(\psi_1^2(D_2)). \end{aligned}$$

*Proof.* Using the pullback property (see Silverman [36] p. 33) and following the same proof as the Lemma 1 in [2], we obtain (up to a scalar multiple in  $\mathbb{F}_p^*$ )

$$\begin{aligned} f_{\lambda_1, [\lambda_1] D_1} \circ \psi_1 &= f_{\lambda_1, D_1}, \\ f_{\lambda_1, [\lambda_1^2] D_1} \circ \psi_1^2 &= f_{\lambda_1, D_1}, \\ f_{\lambda_1, [\lambda_1^3] D_1} \circ \psi_1^3 &= f_{\lambda_1, D_1}. \end{aligned}$$

Using the relations between the isogeny  $\psi_1$  and its dual isogeny  $\widehat{\psi}_1$  (see Section 3.2), we have

$$\begin{aligned} f_{\lambda_1, [\lambda_1] D_1} \circ \psi_1 \circ \widehat{\psi}_1 &= f_{\lambda_1, [\lambda_1] D_1} = f_{\lambda_1, D_1} \circ \widehat{\psi}_1, \\ f_{\lambda_1, [\lambda_1^2] D_1} \circ \psi_1^2 \circ \widehat{\psi}_1^2 &= f_{\lambda_1, [\lambda_1^2] D_1} = f_{\lambda_1, D_1} \circ \widehat{\psi}_1^2, \\ f_{\lambda_1, [\lambda_1^3] D_1} \circ \psi_1^3 \circ \widehat{\psi}_1^3 &= f_{\lambda_1, [\lambda_1^3] D_1} = f_{\lambda_1, D_1} \circ \widehat{\psi}_1^3 = f_{\lambda_1, D_1} \circ \psi_1^2, \end{aligned}$$

which proves the results.

With the above three lemmas, we can now prove the statement of Theorem 1 as follows:

*Proof (of Theorem 1).* For  $D_1 \in \mathcal{J}_{C'_1}(\mathbb{F}_p)[n]$  and  $D_2 \in \mathcal{J}_{C'_1}(\mathbb{F}_{p^k})$ , Lemma 3 shows that

$$\begin{aligned} f_{\lambda_1, [\lambda_1] D_1}(D_2) &= f_{\lambda_1, D_1}(\widehat{\psi}_1(D_2)), \\ f_{\lambda_1, [\lambda_1^2] D_1}(D_2) &= f_{\lambda_1, D_1}(\widehat{\psi}_1^2(D_2)), \\ f_{\lambda_1, [\lambda_1^3] D_1}(D_2) &= f_{\lambda_1, D_1}(\psi_1^2(D_2)), \end{aligned}$$

Now, substituting the above three equalities into Lemma 2 implies that

$$f_{\lambda_1^4 + \lambda_1^3 + \lambda_1^2 + \lambda_1, D_1}(D_2) \cdot u_1(D_2) = f_{\lambda_1, D_1}^{\lambda_1^3 + \lambda_1^2 + \lambda_1 + 1}(D_2) \cdot f_{\lambda_1, D_1}^{\lambda_1^2 + \lambda_1 + 1}(\widehat{\psi}_1(D_2)) \cdot f_{\lambda_1, D_1}^{\lambda_1 + 1}(\widehat{\psi}_1^2(D_2)) \cdot f_{\lambda_1, D_1}(\psi_1^2(D_2)) \cdot g(D_2).$$

Finally, substituting the above equation into Lemma 1 gives the result of Theorem 1.

Next, we consider how to use the efficiently-computable automorphism  $\psi_2$  to accelerate the computation of the Tate pairing on the curve  $C'_2$ . The following Theorem 2 describes our result.

**Theorem 2.** *Let  $C'_2$  be a non-supersingular genus 2 hyperelliptic curve over  $\mathbb{F}_p$  as above, with embedding degree  $k > 1$  and automorphisms  $\psi_2$  and  $\widehat{\psi}_2$  defined as above. Let  $D_1 = [u_1(x), v_1(x)] \in \mathcal{J}_{C'_2}(\mathbb{F}_p)$  be a reduced divisor of prime order  $n$ , where  $n^2 \nmid \#\mathcal{J}_{C'_2}(\mathbb{F}_p)$ . Let  $[\lambda_2]$  act as the multiplication map on the subgroup  $\langle D_1 \rangle$  defined as above such that  $[\lambda_2]D_1 = \psi_2(D_1)$ . Suppose  $m \in \mathbb{Z}$  is such that  $mn = \lambda_2^4 + 1$ . Then for  $D_2 \in \mathcal{J}_{C'_2}(\mathbb{F}_{p^k})$ , we have*

$$\langle D_1, D_2 \rangle_n^{\frac{m(p^k-1)}{n}} = \left[ f_{\lambda_2, D_1}^{\lambda_2^3}(D_2) \cdot f_{\lambda_2, D_1}^{\lambda_2^2}(\widehat{\psi}_2(D_2)) \cdot f_{\lambda_2, D_1}^{\lambda_2}(\widehat{\psi}_2^2(D_2)) \cdot f_{\lambda_2, D_1}(\widehat{\psi}_2^3(D_2)) \cdot u_1(D_2) \right]^{\frac{p^k-1}{n}}.$$

*Proof.* The proof is similar with that of Theorem 1. Therefore, we omit it here.

From Theorem 1 and Theorem 2, we note that the pairing computation on curve  $C'_2$  is more efficient than that on curve  $C'_1$ . Hence, the following discussions only focus on the curve  $C'_2$ .

## 4.2 A New Variant of Miller's Algorithm

In this subsection, we propose a new variant of Miller's algorithm for the family of genus 2 hyperelliptic curves  $C'_2$  over  $\mathbb{F}_p$  with efficiently computable automorphisms  $\psi_2$  and  $\widehat{\psi}_2$ . From Theorem 2, we obtain the following new algorithm for computing the Tate pairing on such curves  $C'_2$ , which is a variant of Miller's Algorithm (see Algorithm 1 in Section 2.2).

---

### Algorithm 2 Computing the Tate Pairing with Efficient Automorphisms

---

IN:  $\overline{D}_1 = [u_1, v_1] \in \mathcal{J}_{C'_2}(\mathbb{F}_p)[n]$ ,  $\overline{D}_2 \in \mathcal{J}_{C'_2}(\mathbb{F}_{p^k})$ , represented by  $D_1$  and  $D_2$  with  $\text{supp}(D_1) \cap \text{supp}(D_2) = \emptyset$ ,  
 $\lambda_2 = (e_r, e_{r-1}, \dots, e_0)_2$ , where  $e_i \in \{0, 1\}$  for  $i = 0, \dots, r-1$  and  $e_r = 1$ , and  $mn = \lambda_2^4 + 1$ .

OUT:  $\langle D_1, D_2 \rangle_n^{m(p^k-1)/n}$

1.  $T \leftarrow D_1, f_1 \leftarrow 1, f_2 \leftarrow 1, f_3 \leftarrow 1, f_4 \leftarrow 1, f_5 \leftarrow u_1(D_2)$
  2. **for**  $i$  **from**  $r-1$  **downto**  $0$  **do**
  3.      $\triangleright$  Compute  $T'$  and  $G_{T,T}(x, y)$  such that  $T' = 2T - \text{div}(G_{T,T})$
  4.      $\overline{T} \leftarrow [2]\overline{T}$
  5.      $f_1 \leftarrow f_1^2 \cdot G_{T,T}(D_2), f_2 \leftarrow f_2^2 \cdot G_{T,T}(\widehat{\psi}_2(D_2)), f_3 \leftarrow f_3^2 \cdot G_{T,T}(\widehat{\psi}_2^2(D_2)), f_4 \leftarrow f_4^2 \cdot G_{T,T}(\widehat{\psi}_2^3(D_2))$
  6. **if**  $e_i = 1$  **then**
  7.      $\triangleright$  Compute  $T'$  and  $G_{T,D_1}(x, y)$  such that  $T' = T + D_1 - \text{div}(G_{T,D_1})$
  8.      $\overline{T} \leftarrow \overline{T} \oplus \overline{D}_1$
  9.      $f_1 \leftarrow f_1 \cdot G_{T,D_1}(D_2), f_2 \leftarrow f_2 \cdot G_{T,D_1}(\widehat{\psi}_2(D_2)), f_3 \leftarrow f_3 \cdot G_{T,D_1}(\widehat{\psi}_2^2(D_2)), f_4 \leftarrow f_4 \cdot G_{T,D_1}(\widehat{\psi}_2^3(D_2))$
  10.  $f \leftarrow ((f_1^{\lambda_2} \cdot f_2)^{\lambda_2} \cdot f_3)^{\lambda_2} \cdot f_4 \cdot f_5$
  11.  $f \leftarrow f^{(p^k-1)/n}$
  12. **Return**  $f$
- 

For the curve  $C'_1$ , we can also obtain a similar variant of Miller's algorithm as in Algorithm 2, based on Theorem 1.

## 5 Implementing the Tate Pairing with Efficient Automorphisms

In this section, we describe various techniques that enable the efficient implementation of the Tate pairing on a non-supersingular genus 2 curve of type  $C'_2$  over  $\mathbb{F}_p$ . Furthermore, we also analyze the computational cost of our new algorithm in detail and give timings for our implementation.

## 5.1 Curve Generation

While generating suitable parameters for supersingular genus 2 hyperelliptic curves over prime fields is easy, it seems to be more difficult to generate pairing-friendly non-supersingular genus 2 curves over  $\mathbb{F}_p$  because of the complicated algebraic structure of hyperelliptic curves. Only a few results have appeared in the literature to address this issue [12, 16, 23, 25] and there is ongoing research in this direction. In [12], Freeman proposed the first explicit construction of pairing-friendly genus 2 hyperelliptic curves over prime fields with ordinary Jacobians by modeling on the Cocks-Pinch method for the elliptic curve case [8]. In the appendix of [12], we find two examples which belong to the curve family  $C'_1$  considered in this paper. Unfortunately, the curve parameters in the two examples are too large to be optimal for efficient implementation. In a recent paper [25], Kawazoe and Takahashi presented two different approaches for explicitly constructing pairing-friendly genus 2 curves of the type  $y^2 = x^5 + ax$  over  $\mathbb{F}_p$ . One is an analogue of the Cocks-Pinch method and the other is a cyclotomic method. Their findings are based on the closed formulae [15, 19] for the order of the Jacobian of hyperelliptic curves of the above type. In this paper we will restrict to the case  $p \equiv 1 \pmod{8}$  and generate a suitable non-supersingular pairing-friendly genus 2 hyperelliptic curves  $C'_2$  with embedding degree 4 using the theorems in [25]. The reason that we only consider curves with embedding degree 4 in this section is to facilitate performance comparisons between supersingular and non-supersingular genus 2 curves. However, we would like to point out that non-supersingular curves with higher embedding degree are available from [25] and that our method is also applicable to such curves.

To find good curve parameters which are suitable for applying our new algorithm, we use the following searching strategies. From Theorem 2 we note that the subgroup order  $n$  should satisfy  $mn = \lambda_2^4 + 1$  for an integer  $m$ . Assume that we require the (160/1024) bit security level. Then  $n$  is a prime around 160 bits and  $\lambda_2$  is at least 40 bits. Furthermore, since the bit length of  $\lambda_2$  determines the length of the loop in Algorithm 2,  $\lambda_2$  should be taken as small as possible. Based on these observations, we first check all  $\lambda_2$ 's of the form  $\lambda_2 = 2^a, a \in \{41, 42, \dots, 60\}$ . We found two  $\lambda_2$ 's, namely  $\lambda_2 = 2^{58}$  and  $2^{59}$ , for which  $\lambda_2^4 + 1$  has a prime factor of 164 bits and 162 bits, respectively. However, using the above two primes as the subgroup order  $n$  and running the algorithms of [25], we cannot find any curve. Therefore, we consider the slightly more complicated choice of  $\lambda_2 = 2^a + 2^b$ , where  $a, b \in \{41, 42, \dots, 50\}$  and  $a > b$ . After a couple of trials, we found that choosing  $\lambda_2 = 2^{43} + 2^{10}$  generates a non-supersingular pairing-friendly genus 2 hyperelliptic curve whose Jacobian has embedding degree 4 with respect to a 163-bit prime  $n$ . The curve is given by the equation

$$C_2^* : y^2 = x^5 + 9x$$

over  $\mathbb{F}_p$ , for a 329-bit prime  $p$ , where the hexadecimal representations of  $n$  and  $p$  are as follows

$$\begin{aligned} n &= 00000006 \text{ a37991af } 81ddfa3a \text{ ead6ec83 } 1ca0fc44 \text{ 75d5add9 } \text{ (163 bits)} \\ p &= 0000016b \text{ 953ca333 } \text{ acf202b3 } 0476f30f \text{ ff085473 } 6d0a0be4 \\ &\quad \text{c542fa48 } 66e5afba \text{ 7bc6cd6d } 21ca9fad \text{ eef796f1 } \quad \text{(329 bits)} \end{aligned}$$

In the following five subsections, we will detail various techniques required to efficiently implement the calculation of the Tate pairing on the above curve  $C_2^*$ .

## 5.2 Finite Field Arithmetic

As the embedding degree of the curve  $C_2^*$  in our implementation is  $k = 4$ , we first discuss how to construct the finite field  $\mathbb{F}_{p^4}$ . Rather than construct  $\mathbb{F}_{p^4}$  as a direct quartic extension of  $\mathbb{F}_p$ , the best way is to define the field  $\mathbb{F}_{p^4}$  as a quadratic extension of  $\mathbb{F}_{p^2}$ , which is in turn a quadratic extension of  $\mathbb{F}_p$ . Since the  $p$  is congruent to 5 modulo 12 in our implementation, the field  $\mathbb{F}_{p^2}$  can be constructed by the irreducible binomial  $x^2 + 3$  and the field  $\mathbb{F}_{p^4}$  can be constructed as a quadratic extension of  $\mathbb{F}_{p^2}$  by the irreducible binomial  $x^2 - \sqrt{-3}$ . Letting  $\beta = -3$ , elements of the

field  $\mathbb{F}_{p^2}$  can be represented as  $a + b\sqrt{\beta}$ , where  $a, b \in \mathbb{F}_p$ , whereas elements of the field  $\mathbb{F}_{p^4}$  can be represented as  $c + d\sqrt[4]{\beta}$ , where  $c, d \in \mathbb{F}_{p^2}$ . Under this tower construction, a multiplication of two elements and a squaring of one element in  $\mathbb{F}_{p^4}$  cost  $9M$  and  $6M$  in  $\mathbb{F}_p$ , respectively [21].

### 5.3 Encapsulated Group Operations

In [11], Fan *et. al.* proposed a method to encapsulate the computation of the line function with the group operations for genus 2 hyperelliptic curves over prime fields, and derived new mix-addition and doubling formulae in projective and new (weighted projective) coordinates, respectively. Applying their explicit formulae to the curve  $C_2^*$  defined above, we can respectively calculate the divisor class addition and doubling with  $36M + 5S$  and  $35M + 5S$  in  $\mathbb{F}_p$  in new coordinates. We also include their explicit formulae in the appendix with some modifications for the curve  $C_2^*$ .

### 5.4 Using Degenerate Divisors and Denominator Elimination

For a hyperelliptic curve of genus  $g > 1$ , using a degenerate divisor as the image divisor is more efficient than using a general divisor when evaluating line functions. Frey and Lange [13] discussed in detail when it is permissible to choose a degenerate divisor as the second argument of Miller's algorithm. They also note that, when the embedding degree  $k$  is even, one might choose the second pairing argument from a set  $S = \{(x, y) \in C(\mathbb{F}_{q^k}) \mid x \in \mathbb{F}_{q^{k/2}}, y \in \mathbb{F}_{q^k} \setminus \mathbb{F}_{q^{k/2}}\}$ . Note that the point in the set  $S$  is on the quadratic twist of  $C/\mathbb{F}_{q^{k/2}}$ . When considering  $C_2^*$  as a curve defined over  $\mathbb{F}_{p^2}$ , we can define a quadratic twist of  $C_2^*$  over  $\mathbb{F}_{p^2}$ , denoted by  $C_{2,t}^*$ , as follows

$$C_{2,t}^* : y^2 = x^5 + 9c^4x,$$

where  $c \in \mathbb{F}_{p^2}$  is a quadratic non-residue over  $\mathbb{F}_{p^2}$ . It is known that  $C_{2,t}^*(\mathbb{F}_{p^4}) \cong C_2^*(\mathbb{F}_{p^4})$  and the isomorphism of  $C_{2,t}^*(\mathbb{F}_{p^4})$  and  $C_2^*(\mathbb{F}_{p^4})$  also induces an isomorphism  $\phi$  of  $\mathcal{J}_{C_{2,t}^*}(\mathbb{F}_{p^4})$  and  $\mathcal{J}_{C_2^*}(\mathbb{F}_{p^4})$  [26]. As in [11] we first generate a degenerate divisor class  $\overline{D}_t = [x - x_t, y_t] \in \mathcal{J}_{C_{2,t}^*}(\mathbb{F}_{p^2})$  on the twisted curve  $C_{2,t}^*/\mathbb{F}_{p^2}$ . Then the isomorphism  $\phi$  will map  $\overline{D}_t$  to a degenerate divisor class  $\overline{D}_2 = \phi(\overline{D}_t) = [x - c^{-1}x_t, c^{-5/2}y_t] \in \mathcal{J}_{C_2^*}(\mathbb{F}_{p^4})$  on the curve  $C_2^*$  over  $\mathbb{F}_{p^4}$ . Note that the denominator elimination technique applies in this case since  $x - c^{-1}x_t$  is defined over  $\mathbb{F}_{p^2}$ . Furthermore, we do not need to compute  $f_5 = u_1(D_2) \in \mathbb{F}_{p^2}$  in Algorithm 2 either, for the same reason.

### 5.5 Evaluating Line Functions at A Degenerate Divisor

Here we consider the evaluation of line functions at a degenerate divisor  $D_2 = [x - x_2, y_2] \in \mathcal{J}_{C_2^*}(\mathbb{F}_{p^4})$  generated by the method in Section 5.4, where  $x_2 = c^{-1}x_t \in \mathbb{F}_{p^2}$  and  $y_2 = c^{-5/2}y_t \in \mathbb{F}_{p^4} \setminus \mathbb{F}_{p^2}$ . Moreover, we further assume that in this work  $c = \sqrt{-3}$  is taken as a quadratic non-residue over  $\mathbb{F}_{p^2}$ . Therefore,  $y_2$  has only two non-zero coefficients instead of four in a polynomial basis representation of  $\mathbb{F}_{p^4}$ . Furthermore, since the denominator elimination technique applies in this case, we only need to evaluate the numerators of the rational functions at  $D_2$ . From [11] we know that in new coordinates we can respectively work with the numerators  $c_1(x, y) = (\tilde{r}z_{11})y - ((s'_1z_{11})x^3 + l_2x^2 + l_1x + l_0)$  for group doubling and  $c_2(x, y) = (\tilde{r}z_{21})y - ((s'_1z_{21})x^3 + l_2x^2 + l_1x + l_0)$  for group addition, where  $\tilde{r}, z_{11}, z_{21}, z_{31}, s'_1, l_2, l_1$  and  $l_0$  are from Table 4 and Table 5 in the appendix. Note that in Algorithm 2 we need to evaluate the function  $c_i(x, y)$ ,  $i = 1$  or  $2$  at four image divisors  $D_2 = [x - x_2, y_2]$ ,  $\widehat{\psi}_2(D_2) = [x - \xi_8^{-2}x_2, \xi_8^{-1}y_2]$ ,  $\widehat{\psi}_2^2(D_2) = [x - \xi_8^4x_2, \xi_8^{-2}y_2] = [x + x_2, \xi_8^{-2}y_2]$  and  $\widehat{\psi}_2^3(D_2) = [x - \xi_8^2x_2, \xi_8^{-3}y_2]$  for each iteration of the loop. Hence we have the following relations

$$\begin{aligned} c_i(D_2) &= (\tilde{r}z_{11})y_2 - [(s'_1z_{11})x_2^3 + l_1x_2 + (l_2x_2^2 + l_0)], \\ c_i(\widehat{\psi}_2(D_2)) &= ((\tilde{r}z_{11})y_2)\xi_8^{-1} - [(s'_1z_{11})x_2^3 - l_1x_2]\xi_8^2 - (l_2x_2^2 - l_0), \\ c_i(\widehat{\psi}_2^2(D_2)) &= ((\tilde{r}z_{11})y_2)\xi_8^{-2} + [(s'_1z_{11})x_2^3 + l_1x_2 - (l_2x_2^2 + l_0)], \\ c_i(\widehat{\psi}_2^3(D_2)) &= ((\tilde{r}z_{11})y_2)\xi_8^{-3} + [(s'_1z_{11})x_2^3 - l_1x_2]\xi_8^2 + (l_2x_2^2 - l_0). \end{aligned}$$

We assume that  $x_2^2, x_2^3, \xi_8^{-1}$  and  $\xi_8^2$  are precomputed with  $7M + 2S$  over  $\mathbb{F}_p$ . Since  $x_2, x_2^2$  and  $x_2^3$  are in  $\mathbb{F}_{p^2}$  and  $y_2$  has only two non-zero coefficients in the polynomial basis representation of  $\mathbb{F}_{p^4}$ ,  $c_i(D_2)$  can be computed with  $10M$  over  $\mathbb{F}_p$ . By reusing the intermediate computation results, we can compute  $c_i(\widehat{\psi}_2(D_2)), c_i(\widehat{\psi}_2^2(D_2))$  and  $c_i(\widehat{\psi}_2^3(D_2))$  with  $4M, 2M$  and  $2M$  over  $\mathbb{F}_p$ , respectively. Therefore, the total cost of evaluating the function  $c_i(x, y)$  at the degenerate divisor  $D_2$  is  $18M$  over  $\mathbb{F}_p$  per iteration, with a precomputation of  $7M + 2S$ . For the case of evaluating the rational functions at a general divisor, the reader is referred to [11].

## 5.6 Final Exponentiation

For a genus 2 curve with an embedding degree of  $k = 4$ , the output of Miller's algorithm needs to be raised to the power of  $(p^4 - 1)/n$ . Calculating this exponentiation can follow two steps as shown in [21]. Letting  $f \in \mathbb{F}_{p^4}$  be the output of Miller's algorithm, the first step is to compute  $f^{p^2-1}$  which can be obtained with a conjugation with respect to  $\mathbb{F}_{p^2}$  and  $1I + 1M$  in  $\mathbb{F}_{p^4}$ . The remaining exponentiation to  $(p^2 + 1)/n$  is an expensive operation which can be efficiently computed with the Lucas laddering algorithm [35] for the curve  $C_2^*$  in question.

## 5.7 Performance Analysis and Comparison

In this section, we analyze the computational complexity of the Algorithm 2 for calculating the Tate pairing on non-supersingular genus 2 hyperelliptic curves  $C_2'$  and compare the performance of pairing computations on supersingular and non-supersingular genus 2 curves over prime fields with the same embedding degree of  $k = 4$ .

We first analyze the algebraic complexity of the pairing computation on curves  $C_2'$  with our new algorithm (see Section 4.2). Recall that  $n$  is the subgroup order and  $\lambda_2$  is a root of the equation  $\lambda^4 + 1 \equiv 0 \pmod{n}$ . We assume that the embedding degree  $k$  is even and the line functions in Algorithm 2 are evaluated at a degenerate divisor  $D_2$  instead of a general divisor for efficiency reasons. We also assume that  $\lambda_2$  has a random Hamming weight, meaning that about  $(\frac{1}{2} \log_2 \lambda_2)$  additions take place in Algorithm 2 on average. Then the algebraic cost for computing the Tate pairing is given as (without including the cost of the final exponentiation)

$$T_1 + (\log_2 \lambda_2)(T_D + T_G + 4T_{sk} + 8T_{mk}) + \left(\frac{1}{2} \log_2 \lambda_2\right) (T_A + T_G + 8T_{mk}) + T_{10},$$

where

1.  $T_2$  – the cost of precomputing  $f_5$  in Step 1 of Algorithm 2.
2.  $T_D$  – the cost of doubling a general divisor.
3.  $T_A$  – the cost of adding two general divisors.
4.  $T_G$  – the cost of evaluating rational function  $G(x, y)$  at the image divisors  $D_2, \widehat{\psi}_2(D_2), \widehat{\psi}_2^2(D_2)$  and  $\widehat{\psi}_2^3(D_2)$ .
5.  $T_{sk}$  – the cost of squaring in  $\mathbb{F}_{p^k}$ .
6.  $T_{mk}$  – the cost of multiplication in  $\mathbb{F}_{p^k}$ .
7.  $T_{10}$  – the cost of computing  $f$  in Step 10 of Algorithm 2.

When applying various optimization techniques detailed in previous subsections to the particular curve  $C_2^*$ , we can further reduce the above cost of computing the Tate pairing to

$$43 \cdot (T_D + T_G + 4T_{sk} + 4T_{mk}) + (T_A + T_G + 4T_{mk}) + T_{10},$$

where  $T_D = 35M + 5S, T_A = 36M + 5S, T_G = 18M, T_{sk} = 6M, T_{mk} = 9M$  and  $T_{10} = 828M$ . Furthermore, we also need  $7M + 2S$  for precomputations (see Section 5.5). Note that all multiplications and squarings here are over  $\mathbb{F}_p$ . Therefore, the total cost of computing the Tate pairing with our optimizations is given as  $5784M + 222S$  in  $\mathbb{F}_p$ .

In [6, 11, 21], the authors examined the implementation of the Tate pairing on a family of supersingular genus 2 hyperelliptic curves  $C_1$  (see Section 3.1) over prime fields with embedding degree 4 in affine and projective coordinates, respectively. We compare the performance of pairing computations on the supersingular curve  $C_1$  and the non-supersingular curve  $C_2^*$  in the following Table 1. Note that both curves have the same embedding degree of  $k = 4$ .

**Table 1.** Performance Comparison of Pairing Computation on Curves  $C_1$  and  $C_2^*$  ( $k = 4$ )

Reference	Curve Equation	Coordinate Type	Cost
Choe and Lee [6]	$C_1 : y^2 = x^5 + a,$ $a \in \mathbb{F}_p^*, p \equiv 2, 3 \pmod{5}$	Affine	$240I, 17688M, 2163S$
Ó hÉigartaigh and Scott [21]		Affine	$162I, 10375M, 645S$
Fan, Gong and Jao [11]		Projective	$13449M, 647S$
		New	$12967M, 811S$
This work	$C_2^* : y^2 = x^5 + 9x,$ $p \equiv 1 \pmod{8}$	New	<b><math>5784M, 222S</math></b>

From Table 1, we note that for the same security level the computation of the Tate pairing on the non-supersingular genus 2 curve  $C_2^*$  is algebraically about 56.2% faster than on the supersingular genus 2 curve  $C_1$ , under the assumption that field squarings have cost  $S = 0.8M$ . Therefore, our algorithm improves previous work for pairing computations on genus 2 hyperelliptic curves over prime fields by a considerable margin.

## 5.8 Experimental Results

For verifying our theoretical analysis in Section 5.7, we report implementation results of computing the Tate pairing on the supersingular genus 2 curve  $C_1$  and non-supersingular genus 2 curve  $C_2^*$  in this section. Both curves are defined over  $\mathbb{F}_p$  and have an embedding degree of  $k = 4$ . The code was written in C and *Microsoft Developer Studio 6* was used for compilation and debugging on a Core 2 Duo™@2.67 GHz processor. For the curve  $C_1$  and the (160/1024) bit security level we use the curve parameters that are generated in [21], where the subgroup order  $n = 2^{159} + 2^{17} + 1$  is a Solinas prime [37] and the characteristic  $p$  of the finite field  $\mathbb{F}_p$  is a 256-bit prime. Recall that the curve  $C_2^*$  is defined over a prime field of size 329 bits (see Section 5.1). The operations in the above two prime fields are implemented with various efficient algorithms in [20]. Table 2 shows the timings of our finite field library and the corresponding *MI*-ratio. From Table 2 we note that the *MI*-ratios are sufficiently large for the two prime fields in our implementation that using new coordinates and encapsulated group operations [11] can provide better performance than using affine coordinates in this case.

**Table 2.** Timings of Prime Field  $\mathbb{F}_p$  Library

Curve	# of bits of $p$	Multiplication ( $M$ )	Squaring ( $S$ )	Inversion ( $I$ )	<i>MI</i> -ratio
$C_1$	256	$0.84\mu s$	$0.78\mu s$	$41.9\mu s$	53.7
$C_2^*$	329	$1.40\mu s$	$1.30\mu s$	$64.6\mu s$	46.1

Table 3 summarizes previous work and our experimental results for the implementation of the Tate pairing on the curve  $C_1$  and  $C_2^*$  for the (160/1024) bit security level. All of the timings are given in milliseconds.

**Table 3.** Experimental Results – (160/1024) Security Level

Reference	Curve	Coordinate Type	Subgroup Order	Running Time (ms)
Choi and Lee [6]	$C_1$	Affine	Random	515
Ó hÉigartaigh and Scott [21]	$C_1$	Affine	$n = 2^{159} + 2^{17} + 1$	16
This work	$C_1$	New	$n = 2^{159} + 2^{17} + 1$	14.9
	$C_2^*$	New	$\lambda_2 = 2^{43} + 2^{10}$	13.4

From Table 3, we note that in our implementation the pairing computation on the curve  $C_2^*$  is about 10% faster than that on the curve  $C_1$ , in contrast to the algebraic complexity analysis in Section 5.7. The reason is that the sizes of the fields over which both curves are defined are different. Observe that the curve  $C_2^*$  is defined over a larger prime field than  $C_1$ , which significantly decreases the speed of computing the final exponentiation of the Tate pairing when the curve  $C_2^*$  is used. This explains why our new algorithm only obtains a 10% performance improvement in the implementation. Unfortunately, under current techniques for generating pairing-friendly non-supersingular genus 2 hyperelliptic curves, we cannot find such a curve of the form  $y^2 = x^5 + ax$  defined over a 256-bit prime field with an embedding degree of  $k = 4$ . Nevertheless, despite the unequal field size, our implementation on the curve  $C_2^*$  is still slightly faster, even though strictly speaking a direct comparison between fields of different size is complicated as many factors could affect the comparison one way or another.

## 6 Conclusion

In this paper, we have proposed new variants of Miller’s algorithm for computing the Tate pairing on two families of non-supersingular genus 2 hyperelliptic curves over prime fields with efficiently computable automorphisms. We describe how to use the automorphisms to shorten the length of the main loop of Miller’s algorithm. As a case study, we combine our new algorithm with various optimization techniques in the literature to efficiently implement the Tate pairing on a non-supersingular genus 2 curve  $y^2 = x^5 + 9x$  over  $\mathbb{F}_p$  with an embedding degree of  $k = 4$ . We also analyze the performance for the new algorithm in detail. When compared with pairing computations on supersingular genus 2 curves at the same security level, our new algorithm can obtain 56.2% performance improvements algebraically. Furthermore, favorable experimental results have been obtained for the implementation of the Tate pairing on both a supersingular and a non-supersingular genus 2 curve with embedding degree 4.

## Appendix: Explicit Formulae for Genus 2 Curves over $\mathbb{F}_p$

In this appendix, we give efficient explicit formulae for group operations on genus 2 curves over  $\mathbb{F}_p$  in new coordinates in the context of pairing computations. Table 4 and Table 5 address the cases of new coordinates. Given two divisor classes  $\bar{E}_1$  and  $\bar{E}_2$ , Table 4 computes the divisor class  $\bar{E}_3 = [u_3(x), v_3(x)]$  and the rational function  $l(x)$  such that  $E_1 + E_2 = E_3 + \text{div}\left(\frac{y-l(x)}{u_3(x)}\right)$  in the new coordinate system, where  $l(x) = \frac{s'_1}{rz_{23}}x^3 + \frac{l_2}{rz_{24}}x^2 + \frac{l_1}{rz_{24}}x + \frac{l_0}{rz_{24}}$ . For doubling a reduced divisor class  $E_1$ , Table 5 calculates the divisor class  $\bar{E}_3 = [u_3(x), v_3(x)]$  and the rational function  $l(x)$  such that  $2E_1 = E_3 + \text{div}\left(\frac{y-l(x)}{u_3(x)}\right)$  in projective coordinates, where  $l(x) = \frac{s'_1}{rz_{13}}x^3 + \frac{l_2}{rz_{14}}x^2 + \frac{l_1}{rz_{14}}x + \frac{l_0}{rz_{14}}$ .
