Abstract

In this report we present invalid-curve attacks that apply to the Montgomery ladder elliptic curve scalar multiplication (ECSM) algorithm. An elliptic curve over the binary field is defined using two parameters, namely a and b . We show that with a different “value” for curve parameter a , there exists a cryptographically weaker group in nine of the ten NIST-recommended elliptic curves over \mathbb{F}_{2^m} . Thereafter, we present two attacks that are based on the observation that parameter a is not utilized for the Montgomery ladder algorithms proposed by López and Dahab [13]. We also present the probability of success of such attacks for general and NIST-recommended elliptic curves. In addition we give some countermeasures to resist this attack.

1 Introduction

In 1996 fault analysis attack was introduced by Boneh et al. [3]. This attack is based on fault injection in a device performing an RSA or Rabin digital signature. Biehl et al. [2] proposed the first fault-based attack on elliptic curve cryptography (ECC). Their basic idea is to force, through a fault, a computation in a weaker group where solving the elliptic curve discrete logarithm problem (ECDLP) is feasible. A basic assumption for this attack is that one of the two parameters denoted as b of the governing elliptic curve equation is not involved for point operations formulas. In this way, the computation could be performed

*This work was done when Agustín Domínguez-Oviedo and Bijan Ansari were at the University of Waterloo.

in a cryptographically less secure elliptic curve. Later, Ciet and Joye [4] have shown how to recover the secret key by applying the same principle of invalid-curves but using a less restrictive assumption of unknown but fixed faulty input point.

The invalid-curve attacks presented by Biehl et al. [2] and Ciet and Joye [4] apply to applications where parameter b is not used for the group formulas. However for the Montgomery ladder algorithm used in ECSM, it is not the case since parameter b is utilized. In this report we present fault based attacks that apply to the Montgomery ladder algorithm. Our work takes advantage of the other parameter of the elliptic curve parameter (i.e., a). After a brief review of the Montgomery algorithm, we first present some observations about the NIST-recommended curves over the binary field. Next, we present two invalid-curve based attacks on the target algorithm. Finally, we present some possible countermeasures to the attacks presented in this report.

2 Background

2.1 Montgomery’s ladder algorithm for ECSM

The well known simplified affine form of the Weierstrass equation of non-supersingular elliptic curves over the binary field is

$$y^2 + xy = x^3 + ax^2 + b. \tag{1}$$

The binary double-and-add and the Montgomery ladder algorithms (and their variants) are among the most commonly used schemes for performing ECSM on curves defined by Equation (1). Algorithm 1 below is a description of the Montgomery algorithm in its most basic form.

Algorithm 1. Basic Montgomery’s ladder ECSM

Input: $P \in E(\mathbb{F}_q)$, $k = (k_{t-1} \cdots k_1 k_0)_2$ with $k_{t-1} = 1$.

Output: $Q = kP$.

1. $Q_0 \leftarrow P, Q_1 \leftarrow 2P$.
 2. For $i = t - 2$ downto 0 do
 - 2.1 If $(k_i = 0)$ then
 - 2.1.1 $Q_1 \leftarrow Q_0 \uplus Q_1, Q_0 \leftarrow 2Q_0$;
 - 2.2 Else
 - 2.2.1 $Q_0 \leftarrow Q_0 \uplus Q_1, Q_1 \leftarrow 2Q_1$.
 3. Return(Q_0).
-

In each iteration of the algorithm, the difference between Q_1 and Q_0 is equal to input point P . This fact leads to a formula for the x -coordinate of the sum of two points without their y -coordinates. Below, we present such a formula due to López and Dahab [13].

Let $P = (x, y)$ be the difference between P_1 and P_0 , i.e., $P_1 - P_0 = P$. If P is known, then the x -coordinate of $P_0 \uplus P_1$ can be obtained as:

$$\mathbf{x}(P_0 \uplus P_1) = \begin{cases} x_0^2 + \frac{b}{x_0^2} & \text{if } P_0 = P_1, \\ x + \frac{x_0}{x_0 + x_1} + \left(\frac{x_0}{x_0 + x_1}\right)^2 & \text{if } P_0 \neq P_1. \end{cases} \quad (2)$$

Additionally the y -coordinate of P_0 , y_0 , can be obtained from $P = (x, y)$, and the x -coordinates of P_0 and P_1 (i.e., x_0 and x_1 , respectively) as follows:

$$y_0 = \frac{(x_0 + x) [(x_0 + x)(x_1 + x) + x^2 + y]}{x} + y. \quad (3)$$

As one can clearly see, Equation (2) involves parameter b . As a result, the invalid-curve attacks presented by Biehl et al. [2] and Ciet and Joye [4] do not apply to the Montgomery algorithm.

2.2 Elliptic curve discrete logarithm problem (ECDLP)

The elliptic curve discrete logarithm problem (ECDLP) is based on the difficulty of obtaining k given P and $Q (= kP)$ for some integer k and $P, Q \in E(\mathbb{F}_q)$. This principle has led to schemes equivalent to DLP-based cryptosystems, such as: Diffie-Hellman key exchange [5], ElGamal public key encryption [7], ElGamal digital signatures [7], and DSA [8].

In practice for the ECDLP to be intractable, it is important to select appropriate domain parameters such as the finite field \mathbb{F}_q where the curve E is defined, the curve E itself, and the base point P . When the order n of the base point P is a large prime, the fastest known algorithms to solve the ECDLP, namely the baby-step giant-step [24] and the Pollard's rho [18] algorithms, need $O(\sqrt{n})$ steps. Consequently, for security purposes it is necessary that the size of the underlying finite field be at least the double of the security level in bits. Security level of L bits is referred to as the best algorithm for breaking the system that takes approximately 2^L steps [12]. For example, for achieving an 80-bit security level, the cryptosystem would require an elliptic curve defined over a finite field \mathbb{F}_q , where $q \approx 2^{160}$. With respect to the selection of the elliptic curve E , some types of curves are avoided for cryptographic applications since the ECDLP can be reduced. These curves include supersingular curves [15], anomalous curves [20] [23], and curves over \mathbb{F}_{2^m} for some non-prime values of m [9] [11] [14].

If the order of the base point P does not contain at least a large prime factor, then it is possible to use an extension for ECC of the Silver-Pohlig-Hellman algorithm [17] to solve the ECDLP as presented in Algorithm 2. This algorithm reduces the problem to

subgroups of prime order. Let n be the order of the base point P with a prime factorization $n = \prod_{i=0}^{j-1} p_i^{e_i}$, where $p_i < p_{i+1}$. Suppose that $Q = lP$, where $P, Q \in E(\mathbb{F}_q)$ and $l \in [0, n-1]$. This algorithm obtains during the outer loop, the value of $l \bmod p_i^{e_i}$ for each $0 \leq i \leq j-1$. With these values $l \bmod n$ can be uniquely computed using the CRT. It is important to note that at Step 1.3.2 one EC discrete logarithm needs to be computed. However, this operation is in a subgroup at the most of order p_{j-1} . It can be performed with the fastest known algorithms for ECDLP such as the Pollard's rho algorithm with an expected running time of $O(\sqrt{p_m})$, where p_m is the largest prime divisor of $\text{ord}(P_i)$.

Algorithm 2. Silver-Pohlig-Hellman's algorithm for solving the ECDLP

Input: $P \in E(\mathbb{F}_q)$, $Q \in \langle P \rangle$, $n = \text{ord}(P) = \prod_{i=0}^{j-1} p_i^{e_i}$, where $p_i < p_{i+1}$.

Output: $l \bmod n$.

1. For $i = 0$ to $j - 1$ do
 - 1.1 $Q' \leftarrow \mathcal{O}$, $l_i \leftarrow 0$.
 - 1.2 $P_i \leftarrow (n/p_i)P$.
 - 1.3 For $t = 0$ to $(e_i - 1)$ do
 - 1.3.1 $Q_{t,i} \leftarrow (n/p_i^{t+1})(Q \uplus Q')$.
 - 1.3.2 $W_{t,i} \leftarrow \log_{P_i} Q_{t,i}$. {ECDLP in a subgroup of order $\text{ord}(P_i)$.}
 - 1.3.3 $Q' \leftarrow Q' - W_{t,i}p^tP$.
 - 1.3.4 $l_i \leftarrow l_i + p^tW_{t,i}$.
 2. Use the CRT to solve the system of congruences $l \equiv l_i \pmod{p_i^{e_i}}$. This gives us $l \bmod n$.
 3. Return(l).
-

Example 1 Let E be the curve $y^2 + xy = x^3 + 1$ over the field $\mathbb{F}_{2^{11}}$ given by the polynomial $f(z) = z^{11} + z^2 + 1$. Let us represent the elements of $\mathbb{F}_{2^{11}}$ in hexadecimal form. Consider the point $P = (0x10F, 0x27A)$ whose order is $n = 92 = 2^2 \cdot 23$. Let $Q = (0x1FB, 0x2C6)$. We can use Algorithm 2 to obtain $l = \log_P Q$ as follows:

- During the first loop for $i = 0$ we can obtain $l_0 = l \bmod 2^2$. We can find that $l_0 = W_{0,0} + 2W_{2,0} = 1 + 2 \cdot 0 = 1$.
- For the second loop for $i = 1$ we determine $l_1 = l \bmod 23$. It can be shown that $l_1 = W_{1,0} = 18$.
- Finally we have the following pair of congruences: $l \bmod 4 = 1$ and $l \bmod 23 = 18$. Solving using the CRT we have $l = 41$.

To resist the Silver-Pohlig-Hellman attack one can simply select an elliptic curve E such that its group order, $\#E(\mathbb{F}_{2^m})$, is prime or *almost prime*, i.e., $\#E(\mathbb{F}_{2^m}) = hn$, where n is a prime and h is small [12] (e.g., $h \in [1, 4]$).

3 Parameter a and NIST recommended curves

3.1 Parameter a

Theorem 1 *Let E and \bar{E} be non-supersingular elliptic curves defined over \mathbb{F}_{2^m} . E and \bar{E} given by the equations*

$$\begin{aligned} E : y^2 + xy &= x^3 + ax^2 + b \\ \bar{E} : y^2 + xy &= x^3 + \bar{a}x^2 + \bar{b} \end{aligned}$$

are isomorphic over \mathbb{F}_{2^m} if and only if $\text{Tr}(a) = \text{Tr}(\bar{a})$ and $b = \bar{b}$. If the last conditions are met, then there is an admissible change of variables $(x, y) \rightarrow (x, y + tx)$ that converts E into \bar{E} for some $t \in \mathbb{F}_{2^m}^$ that satisfies $\bar{a} = t^2 + t + a$.*

By Theorem 1 we can state that the number of isomorphism classes for elliptic curves defined by Equation (1) is $2^{m+1} - 2$. The latter comes from the number of possible values for parameter b (i.e., $2^m - 1$) times the possible values of the trace function of parameter a (i.e., 2). With the last observation, for a fixed value of parameter b there are only two isomorphic classes of curves, one for each value of $\gamma \in \{0, 1\}$, where $\text{Tr}(a) = \gamma$. Let us define two representative elliptic curves, E_0 and E_1 , one for each of these isomorphic classes:

$$E_0 : y^2 + xy = x^3 + b \quad (a = 0), \quad (4)$$

$$E_1 : y^2 + xy = x^3 + x^2 + b \quad (a = 1). \quad (5)$$

Lemma 1 *Let E_0 and E_1 be two elliptic curves over \mathbb{F}_{2^m} defined by Equations (4) and (5), respectively.*

- (i) *The only points that $E_0(\mathbb{F}_{2^m})$ and $E_1(\mathbb{F}_{2^m})$ share are \mathcal{O} and $(0, \sqrt{b})$.*
- (ii) *Let $(u, v) \in E_j(\mathbb{F}_{2^m})$, where $u \in \mathbb{F}_{2^m}^*$, $v \in \mathbb{F}_{2^m}$, and $j \in \{0, 1\}$. Then, there does not exist any point in $E_{\bar{j}}(\mathbb{F}_{2^m})$ of the form (u, w) for any $w \in \mathbb{F}_{2^m}$, where $\bar{j} = 1 - j$.*
- (iii) *There exist two points of the form (u, v) and $(u, u + v)$ in either $E_0(\mathbb{F}_{2^m})$ or $E_1(\mathbb{F}_{2^m})$ for each $u \in \mathbb{F}_{2^m}^*$ and some $v \in \mathbb{F}_{2^m}$.*
- (iv) *The orders of $E_0(\mathbb{F}_{2^m})$ and $E_1(\mathbb{F}_{2^m})$ satisfy the following*

$$\#E_0(\mathbb{F}_{2^m}) + \#E_1(\mathbb{F}_{2^m}) = 2^{m+1} + 2. \quad (6)$$

Proof First, if we solve the quadratic expressions resulting from Equations (4) and (5) with $x = 0$, we obtain a unique solution $y = \sqrt{b}$. For $x \neq 0$, Equation (1) has a solution for y if and only if

$$\text{Tr}(x) + \text{Tr}(a) + \text{Tr}\left(\frac{b}{x^2}\right) = 0. \quad (7)$$

Since the only difference between Equations (4) and (5) is the value of parameter a , we can conclude from Equation (7) that if any value of $x \in \mathbb{F}_{2^m}^*$ does not have a solution with $a = j$, then it does with $a = \bar{j}$ for $j = 0$ or 1 . Also this equation shows that it is not possible to have a solution for both E_0 and E_1 with the same $x \neq 0$.

Additionally, for a given value of $x \neq 0$ we have two distinct solutions that represent two elliptic curve points (i.e., a point and its negative). To this end, for $x \neq 0$, $\#E_0(\mathbb{F}_{2^m}) + \#E_1(\mathbb{F}_{2^m})$ consider exactly $2^{m+1} - 2$ points on both curves. In addition, the points \mathcal{O} and $(0, \sqrt{b})$ are common and are counted twice in the sum of both orders, bringing the total up to $2^{m+1} + 2$ as shown in Equation (6). \square

Example 2 *Let us consider \mathbb{F}_{2^5} as represented by the irreducible polynomial $f(z) = z^5 + z^2 + 1$. Let us represent the elements of \mathbb{F}_{2^5} in hexadecimal form. Let E_0 and E_1 be the curves $y^2 + xy = x^3 + 1$ and $y^2 + xy = x^3 + x^2 + 1$, respectively, defined over \mathbb{F}_{2^5} . $E_0(\mathbb{F}_{2^5})$ has an order of 44 with the following set of points:*

$$\{(0x00, 0x01), (0x01, 0x00), (0x01, 0x01), (0x02, 0x1F), (0x02, 0x1D), (0x03, 0x0C), (0x03, 0x0F), (0x04, 0x12), (0x04, 0x16), (0x05, 0x1A), (0x05, 0x1F), (0x07, 0x1F), (0x07, 0x18), (0x09, 0x1D), (0x09, 0x14), (0x0B, 0x16), (0x0B, 0x1D), (0x0C, 0x05), (0x0C, 0x09), (0x0D, 0x0B), (0x0D, 0x06), (0x0F, 0x19), (0x0F, 0x16), (0x10, 0x09), (0x10, 0x19), (0x11, 0x03), (0x11, 0x12), (0x12, 0x14), (0x12, 0x06), (0x15, 0x12), (0x15, 0x07), (0x17, 0x0B), (0x17, 0x1C), (0x18, 0x0F), (0x18, 0x17), (0x1A, 0x11), (0x1A, 0x0B), (0x1B, 0x0F), (0x1B, 0x14), (0x1C, 0x09), (0x1C, 0x15), (0x1F, 0x06), (0x1F, 0x19), \mathcal{O}\}.$$

On the other hand, $E_1(\mathbb{F}_{2^5})$ has an order of 22 with the following set of points:

$$\{(0x00, 0x01), (0x06, 0x10), (0x06, 0x16), (0x08, 0x17), (0x08, 0x1F), (0x0A, 0x18), (0x0A, 0x12), (0x0E, 0x07), (0x0E, 0x09), (0x13, 0x1C), (0x13, 0x0F), (0x14, 0x0D), (0x14, 0x19), (0x16, 0x02), (0x16, 0x14), (0x19, 0x04), (0x19, 0x1D), (0x1D, 0x1B), (0x1D, 0x06), (0x1E, 0x15), (0x1E, 0x0B), \mathcal{O}\}$$

3.2 NIST recommended curves

Let $E(a, b)$ be a NIST-recommended elliptic curve defined over the binary field \mathbb{F}_{2^m} with curve parameters a and b . In Table 1 each NIST-recommended randomly chosen elliptic curve over \mathbb{F}_{2^m} is presented, where $m = 163, 233, 283, 409$ and 571 . Then, for each of these curves its corresponding curve $\widehat{E}(\widehat{a}, b)$ is shown, where $\widehat{a} = 1 - \text{Tr}(a)$. Similarly, Table 2 gives the NIST-recommended Koblitz curves. For each curve the “values” of m , $f(z)$, a , b , and $\#E(\mathbb{F}_{2^m})$ are listed, where $f(z)$ is the irreducible trinomial or pentanomial used as the reduction polynomial. For the random curves, parameter b is shown in hexadecimal form. For each case the group order $\#E(\mathbb{F}_{2^m})$ is given in decimal, followed by its prime factorization.

We notice that for each listed NIST-recommended curve E , the group $\widehat{E}(\mathbb{F}_{2^m})$ is cryptographically weaker, i.e., all the prime factors of $\#\widehat{E}(\mathbb{F}_{2^m})$ are smaller than the larger prime factor of $\#E(\mathbb{F}_{2^m})$, with only one exception for the case of $m = 283$ for Koblitz curves, where the orders of both $E(\mathbb{F}_{2^m})$ and $\widehat{E}(\mathbb{F}_{2^m})$ are *almost* prime. In Table 3, the size of each prime factor of the group orders of these elliptic curves is presented. Additionally, it can be shown

by Rück's theorem [19] that $E(\mathbb{F}_{2^m})$ and $\widehat{E}(\mathbb{F}_{2^m})$, where $m \in \{163, 233, 283, 409, 571\}$, are cyclic groups for all the curves in Tables 1 and 2.

3.3 Invalid-curve attacks on Montgomery's ladder algorithm

Consider a cryptosystem that uses a *strong* elliptic curve $E(a, b)$ defined over \mathbb{F}_{2^m} with curve parameters a and b (e.g., a NIST-recommended elliptic curve), where m is an odd number. Assume that $\widehat{E}(\widehat{a}, b)$ is a weaker curve defined over \mathbb{F}_{2^m} with curve parameters \widehat{a} and b , such that $\text{Tr}(\widehat{a}) = 1 - \text{Tr}(a)$. Consider that the attacker has the computational power for computing the EC discrete logarithm using the Silver-Pohlig-Hellman algorithm in the cryptographically weaker group $\widehat{E}(\mathbb{F}_{2^m})$. Also consider that $\widehat{E}(\mathbb{F}_{2^m})$ is a cyclic group, which implies that there are $\phi(\#\widehat{E}(\mathbb{F}_{2^m}))$ points of order $\#\widehat{E}(\mathbb{F}_{2^m})$. Additionally, for the attacks presented in this work we need to obtain $\#\widehat{E}(\mathbb{F}_{2^m})$. Using Equation (6), this value can be obtained from $\#E(\mathbb{F}_{2^m})$ which is usually public or can be obtained with some point counting algorithms, e.g., [22] [21]. Consider that the underlying ECSM algorithm is the Montgomery ladder (Algorithm 1). Since this algorithm do not utilize the curve parameter a , depending of the input point the computation can be carried out in either $E(\mathbb{F}_{2^m})$ or $\widehat{E}(\mathbb{F}_{2^m})$. Then, the idea behind the attacks presented below is to produce an incorrect result from the computation being performed in $\widehat{E}(\mathbb{F}_{2^m})$ due to a fault.

Example for $m = 163$: $f(z) = z^{163} + z^7 + z^6 + z^3 + 1$,

Table 3: Size of each prime factor of $\#E(\mathbb{F}_{2^m})$ and $\#\widehat{E}(\mathbb{F}_{2^m})$ (in bits) for the examples of Tables 1 and 2

4 Basic attack

Fault model Let us assume that the adversary can inject a flip-fault (single or multiple bit) into the x -coordinate of the input point $P = (P_x, P_y) \in E(\mathbb{F}_{2^m})$ of a device computing the ECSM utilizing Algorithm 1. Suppose that the resulting finite field pair after the fault injection is known and is $\tilde{P} = (\tilde{P}_x, P_y)$. Consider that the result $\tilde{Q} = k\tilde{P} = (\tilde{Q}_x, \tilde{Q}_y)$ is released.

4.1 Attack description

For a given $\tilde{P} = (\tilde{P}_x, P_y)$ we can verify if there exists a point in $\widehat{E}(\mathbb{F}_{2^m})$ with the same x -coordinate, i.e., if $\exists \hat{P} \in \widehat{E}(\mathbb{F}_{2^m})$ such that $\hat{P} = (\tilde{P}_x, \hat{P}_y)$ for some $\hat{P}_y \in \mathbb{F}_{2^m}$. In fact, by Lemma 1 we can expect that if we flip single or multiple bits of the x -coordinate such a point exists with a probability of about $1/2$. When $\hat{P} \in \widehat{E}(\mathbb{F}_{2^m})$, in a similar way we can obtain $\hat{Q} = (\tilde{Q}_x, \hat{Q}_y) \in \widehat{E}(\mathbb{F}_{2^m})$ for some $\hat{Q}_y \in \mathbb{F}_{2^m}$.

Having $\widehat{P}, \widehat{Q} \in \widehat{E}(\mathbb{F}_{2^m})$ one can obtain $l = k$ or $\#\widehat{E}(\mathbb{F}_{2^m}) - k \bmod n$ using Algorithm 2, where $n = \text{ord}(\widehat{P})$. This would be possible because the computation is performed in the weaker group $\widehat{E}(\mathbb{F}_{2^m})$ and not in the original group $E(\mathbb{F}_{2^m})$. One can then exhaustively search for an integer k' that satisfies (i) $l = k' \bmod n$ or $\#\widehat{E}(\mathbb{F}_{2^m}) - k' \bmod n$ and (ii) $\widetilde{Q} = k'\widetilde{P}$. Thus, the idea of the basic attack is that the adversary with only one pair $(\widehat{P}, \widehat{Q})$ and some acceptable amount of exhaustive search will be able to retrieve the secret scalar k with a probability of success ρ . Let e be a parameter such that 2^e is the maximum acceptable amount of exhaustive search space. The complete attack procedure is presented as Algorithm 3.

In Step 8 of Algorithm 3, $l = k$ or $\#\widehat{E}(\mathbb{F}_{2^m}) - k \bmod n$ is obtained. The value of l has only partial information about k . The remaining part of the scalar might be obtained using an exhaustive search. The latter involves two main steps: (i) solve a system congruences with a test candidate and the known part of the scalar (Step 11.2.1), and (ii) perform a scalar multiplication to verify if the solution of the system of congruences is the desired scalar (Step 11.2.2).

Let r be the exhaustive search space. This value depends on n and $\#\widehat{E}(\mathbb{F}_{2^m})$. In Step 11.2.1, for having a unique solution $\bmod \#\widehat{E}(\mathbb{F}_{2^m})$ it is necessary that

$$\text{lcm}(n, r) = \#\widehat{E}(\mathbb{F}_{2^m}). \quad (8)$$

Algorithm 3. Basic invalid-curve attack on Montgomery's ladder ECSM algorithm

Input: E defined over \mathbb{F}_{2^m} , access to Algorithm 1, the base point $P = (P_x, P_y) \in E(\mathbb{F}_{2^m})$, the order $\#\widehat{E}(\mathbb{F}_{2^m})$, a parameter for acceptable amount of exhaustive search e .

Output: Scalar k with a probability of ρ .

Phase 1: Collect faulty output

1. Inject a fault in $P = (P_x, P_y)$ for obtaining $\widetilde{P} = (\widetilde{P}_x, P_y)$.
2. Compute $\widetilde{Q} = k\widetilde{P} = (\widetilde{Q}_x, \widetilde{Q}_y)$ Algorithm 1.
3. $T \leftarrow \widetilde{Q}_x + b/\widetilde{Q}_x^2 + \widehat{a}$.
4. If $(\text{Tr}(T) = 0)$ then
 - 4.1 $\widehat{Q}_x \leftarrow \widetilde{Q}_x, \widehat{Q}_y \leftarrow \widetilde{Q}_x \cdot \text{Ht}(T)$;
5. Else
 - 5.1 Go to Step 1.

Phase 2: Obtain k partially using the Silver-Pohlig-Hellman algorithm

6. $\widehat{P}_x \leftarrow \widetilde{P}_x, \widehat{P}_y \leftarrow \widetilde{P}_x \cdot \text{Ht}(\widetilde{P}_x + b/\widetilde{P}_x^2 + \widehat{a})$.

7. Obtain $n = \text{ord}(\widehat{P})$.
8. Utilize Algorithm 2 with $(\widehat{P}, \widehat{Q}, n)$ to obtain $l \bmod n$.

Phase 3: Exhaustive search and verification

9. Find the smallest value of r for $\text{lcm}(n, r) = \#\widehat{E}(\mathbb{F}_{2^m})$ (see Equation (10)).
10. If $(r = 1)$ then
 - 10.1 Compute $R = l\widetilde{P}$ using Algorithm 1.
 - 10.2 If $(R = \widetilde{Q})$ then return(l); else return($\#\widehat{E}(\mathbb{F}_{2^m}) - l$).
11. Else if $(r \leq 2^e)$ then
 - 11.1 $k' \leftarrow 0$.
 - 11.2 While $(k' < r)$ do
 - 11.2.1 Solve the system of congruences $k'' \equiv k' \pmod{r}$ and $k'' \equiv l \pmod{n}$.
 - 11.2.2 Compute $R = k''\widetilde{P}$ using Algorithm 1.
 - 11.2.3 If $(R = \widetilde{Q})$ then return(k'');
 - 11.2.4 Else if $(R = -\widetilde{Q})$ then return($\#\widehat{E}(\mathbb{F}_{2^m}) - k''$);
 - 11.2.5 Else $k' \leftarrow k' + 1$.
12. Else return("failure").

For efficiency r should be selected as the minimum value that satisfies Equation (8). Let $\#\widehat{E}(\mathbb{F}_{2^m}) = 2^{e_0} p_1^{e_1} p_2^{e_2} \cdots p_{u-1}^{e_{u-1}}$ be the prime factorization of $\#\widehat{E}(\mathbb{F}_{2^m})$, where $e_j \geq 1$ for $j \in [0, u-1]$. Let $n = 2^{f_0} p_1^{f_1} p_2^{f_2} \cdots p_{u-1}^{f_{u-1}}$ be the prime factorization of $n = \text{ord}(\widehat{P})$, where $0 \leq f_j \leq e_j$ for $j \in [0, u-1]$. Similarly, let $r = 2^{g_0} p_1^{g_1} p_2^{g_2} \cdots p_{u-1}^{g_{u-1}}$ be the prime factorization of r . Using notations similar to those utilized by Menezes et al. [16] with regard to lcm , we can express Equation (8) as

$$2^{\max(f_0, g_0)} p_1^{\max(f_1, g_1)} p_2^{\max(f_2, g_2)} \cdots p_{u-1}^{\max(f_{u-1}, g_{u-1})} = 2^{e_0} p_1^{e_1} p_2^{e_2} \cdots p_{u-1}^{e_{u-1}}. \quad (9)$$

The exponents of the minimum value of r that satisfies Equation (9) are

$$g_j = \begin{cases} 0 & \text{if } e_j = f_j, \\ e_j & \text{otherwise,} \end{cases} \quad (10)$$

for $j \in [0, u-1]$.

Note that if $r > 2^e$, Algorithm 3 returns in Step 12 "failure". This means that from a specific pair $(\widetilde{P}, \widetilde{Q})$ the exhaustive search space required to obtain uniquely the value of k (i.e., r) is more than the maximum admissible exhaustive search space (i.e., 2^e). For

example for a weaker group $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves, as we show below, the probability of failure is quite low even for small values of e . Moreover, in the case of not success with a particular pair $(\widetilde{P}, \widetilde{Q})$, the attacker can repeat the attack procedure until an inevitable success.

The probability of success of Algorithm 3 (i.e., ρ), depends on the maximum acceptable amount of exhaustive search 2^e and the order of point \widehat{P} . Assume that point \widehat{P} is taken randomly from group $\widehat{E}(\mathbb{F}_{2^m})$. In a cyclic group, it is well known that the number of elements of order d is $\phi(d)$. Here $\#\widehat{E}(\mathbb{F}_{2^m})$ is not prime, and consequently not all the points in $\widehat{E}(\mathbb{F}_{2^m})$ have an order $\#\widehat{E}(\mathbb{F}_{2^m})$. Moreover, if $\#\widehat{E}(\mathbb{F}_{2^m})$ has several prime factors (i.e., it is expected since $\widehat{E}(\mathbb{F}_{2^m})$ is assumed to be a weaker group), the order of the points could have any combination of those prime factors or their respective prime powers. For example the number of points with the full order $\#\widehat{E}(\mathbb{F}_{2^m})$ is $\phi(\#\widehat{E}(\mathbb{F}_{2^m}))$. In contrast, there is only one point of order two which corresponds to $(0, \sqrt{b})$.

4.2 Obtaining the probability of success ρ

Let $\#\widehat{E}(\mathbb{F}_{2^m}) = 2^{n_0} p_1^{n_1} p_2^{n_2} \cdots p_{u-1}^{n_{u-1}}$ be the prime factorization of $\#\widehat{E}(\mathbb{F}_{2^m})$, where $n_j \geq 1$ for $j \in [0, u-1]$ and $p_j < p_{j+1}$ for $j \in [1, u-2]$. Assume that point \widehat{P} is taken randomly from the group $\widehat{E}(\mathbb{F}_{2^m})$. Here we will obtain the probability of success ρ , first for specific values and then for an arbitrary value of e .

- *Case 1: $e = 0$.* If $e = 0$, then the attack will succeed when $\text{ord}(\widehat{P}) = \#\widehat{E}(\mathbb{F}_{2^m})$. The number of points in $\widehat{E}(\mathbb{F}_{2^m})$ of order $\#\widehat{E}(\mathbb{F}_{2^m})$ is

$$\phi(\#\widehat{E}(\mathbb{F}_{2^m})) = 2^{n_0-1} \prod_{j=1}^{u-1} p_j^{n_j} \left(1 - \frac{1}{p_j}\right),$$

and for this case the probability ρ is

$$\rho_{e=0} = \frac{\phi(\#\widehat{E}(\mathbb{F}_{2^m}))}{\#\widehat{E}(\mathbb{F}_{2^m})} = \frac{1}{2} \prod_{j=1}^{u-1} \left(1 - \frac{1}{p_j}\right). \quad (11)$$

Clearly this value is bounded to $1/2$. If $p_1 \gg 1$, then $\rho_{e=0}$ would be close to $1/2$ (e.g., all the Koblitz curves in Example 4.2).

- *Case 2: $e = 1$.* For $e = 1$, this probability can be obtained as follows

$$\rho_{e=1} = \begin{cases} \prod_{j=1}^{u-1} \left(1 - \frac{1}{p_j}\right), & \text{if } n_0 = 1, \\ \frac{1}{2} \prod_{j=1}^{u-1} \left(1 - \frac{1}{p_j}\right), & \text{otherwise.} \end{cases} \quad (12)$$

- *Case 3: $e = 2$.* For $e = 2$ we can have two cases. First, if $p_1 \neq 3$, then $\rho_{e=2}$ is

$$\rho_{e=2} = \begin{cases} \prod_{j=1}^{u-1} \left(1 - \frac{1}{p_j}\right), & \text{if } n_0 = 1 \text{ or } 2, \\ \frac{1}{2} \prod_{j=1}^{u-1} \left(1 - \frac{1}{p_j}\right), & \text{otherwise.} \end{cases} \quad (13)$$

Secondly, if $p_1 = 3$, then it is necessary to take into account points of order $\#\widehat{E}(\mathbb{F}_{2^m})/h$, with $h \in [1, 3]$. In this case $\rho_{e=2}$ is

$$\rho_{e=2} = \begin{cases} \frac{5}{6} \prod_{j=2}^{u-1} \left(1 - \frac{1}{p_j}\right), & \text{if } n_0 = 1 \text{ or } 2, \text{ and } n_1 = 1, \\ \frac{2}{3} \prod_{j=2}^{u-1} \left(1 - \frac{1}{p_j}\right), & \text{if } n_0 = 1 \text{ or } 2, \text{ and } n_1 \geq 2, \\ \frac{1}{6} \prod_{j=2}^{u-1} \left(1 - \frac{1}{p_j}\right), & \text{if } n_0 \geq 3, \text{ and } n_1 = 1, \\ \frac{1}{3} \prod_{j=2}^{u-1} \left(1 - \frac{1}{p_j}\right), & \text{otherwise.} \end{cases} \quad (14)$$

- *Case 4: Arbitrary e with some conditions.* Let

$$\#\widehat{E}(\mathbb{F}_{2^m}) = 2^{n_0} p_1^{n_1} p_2^{n_2} \cdots p_{t-1}^{n_{t-1}} p_t^{n_t} p_{t+1}^{n_{t+1}} \cdots p_{u-1}^{n_{u-1}}.$$

Assume that $\#\widehat{E}(\mathbb{F}_{2^m})$ splits completely in e bits such that

$$\log_2(2^{n_0} p_1^{n_1} \cdots p_{t-1}^{n_{t-1}}) \leq e \text{ and } \log_2(p_t) > e.$$

If these conditions are satisfied, then the number of points whose order divides $p_t^{n_t} p_{t+1}^{n_{t+1}} \cdots p_{u-1}^{n_{u-1}}$ is

$$s = \sum_{i=0}^{g-1} \phi \left(2^{j_0(i)} p_1^{j_1(i)} p_2^{j_2(i)} \cdots p_{t-1}^{j_{t-1}(i)} p_t^{n_t} p_{t+1}^{n_{t+1}} \cdots p_{u-1}^{n_{u-1}} \right), \quad (15)$$

where

$$\begin{aligned}
g &= (n_0 + 1)(n_1 + 1) \cdots (n_{t-1} + 1) \\
j_0(i) &= i \bmod (n_0 + 1), \\
j_1(i) &= \left\lfloor \frac{i}{n_0 + 1} \right\rfloor \bmod (n_1 + 1), \\
j_2(i) &= \left\lfloor \frac{i}{(n_0 + 1)(n_1 + 1)} \right\rfloor \bmod (n_2 + 1), \\
&\vdots \\
j_{t-1}(i) &= \left\lfloor \frac{i}{(n_0 + 1)(n_1 + 1) \cdots (n_{t-2} + 1)} \right\rfloor \bmod (n_{t-1} + 1).
\end{aligned}$$

It can be shown that

$$\sum_{i=0}^{g-1} \phi \left(2^{j_0(i)} p_1^{j_1(i)} p_2^{j_2(i)} \cdots p_{t-1}^{j_{t-1}(i)} \right) = 2^{n_0} p_1^{n_1} p_2^{n_2} \cdots p_{t-1}^{n_{t-1}}$$

Since the function ϕ is *multiplicative*¹ we can reduce Equation (15) and obtain

$$s = 2^{n_0} p_1^{n_1} \cdots p_{t-1}^{n_{t-1}} p_t^{n_t-1} (p_t - 1) p_{t+1}^{n_{t+1}-1} (p_{t+1} - 1) \cdots p_{u-1}^{n_{u-1}-1} (p_{u-1} - 1).$$

In this case ρ is as follows,

$$\rho = \frac{s}{\#\widehat{E}(\mathbb{F}_{2^m})} = \frac{(p_t - 1)(p_{t+1} - 1) \cdots (p_{u-1} - 1)}{p_t p_{t+1} \cdots p_{u-1}}. \quad (16)$$

- *Case 5: Arbitrary e .* When we cannot split $\#\widehat{E}(\mathbb{F}_{2^m})$ in the form as in the previous case we can proceed as follows. First, search for the smallest prime factor such that $\log_2(p_i) > e$. Let t be the index of such prime factor. Let $d = p_t^{n_t} p_{t+1}^{n_{t+1}} \cdots p_{u-1}^{n_{u-1}}$. From all the possible combinations of the prime factors $p_0 p_1 \cdots p_{t-1}$ and their respective powers, we need to consider only those whose product with d have a value of r that satisfies Equation (8) and $r \leq e$. The complete procedure for this case is stated in Algorithm 4. This algorithm also includes the computation of ρ for Cases 1-4.

Algorithm 4. Probability of success ρ for Algorithm 3

Input: The order $\#\widehat{E}(\mathbb{F}_{2^m}) = 2^{n_0} p_1^{n_1} p_2^{n_2} \cdots p_{t-1}^{n_{t-1}} p_t^{n_t} p_{t+1}^{n_{t+1}} \cdots p_{u-1}^{n_{u-1}}$, a parameter for acceptable amount of exhaustive search e , where $0 \leq e < \log_2(p_{u-1})$.

Output: Probability of success ρ .

¹If $\gcd(m, n) = 1$, then $\phi(mn) = \phi(m)\phi(n)$.

1. If ($e = 0$) then return($\rho_{e=0}$) using Equation (11);
 2. Else if ($e = 1$) then return($\rho_{e=1}$) using Equation (12);
 3. Else if ($e = 2$) then return($\rho_{e=2}$) using Equation (13) or (14);
 4. Else if $\#\widehat{E}(\mathbb{F}_{2^m})$ splits completely in e bits such that $\log_2(2^{n_0}p_1^{n_1} \cdots p_{t-1}^{n_{t-1}}) \leq e$ and $\log_2(p_t) > e$
 - 4.1 Return(ρ) using Equation (16);
 5. Else
 - 5.1 Search for the smallest prime factor such that $\log_2(p_i) > e$. Set t with this index.
 - 5.2 $d \leftarrow p_t^{n_t} p_{t+1}^{n_{t+1}} \cdots p_{u-1}^{n_{u-1}}$.
 - 5.3 $\rho \leftarrow 0$.
 - 5.4 For $j_{t-1} = 0$ to n_{t-1} do
 - For $j_{t-2} = 0$ to n_{t-2} do

 - For $j_0 = 0$ to n_0 do
 - $h \leftarrow 2^{j_0} p_1^{j_1} \cdots p_{t-2}^{j_{t-2}} p_{t-1}^{j_{t-1}}$.
 - Find the smallest value of r for $\text{lcm}(d \cdot h, r) = \#\widehat{E}(\mathbb{F}_{2^m})$.
 - If ($r \leq 2^e$) then
 - $\rho \leftarrow \rho + \phi(h)$.
 - 5.5 $\rho \leftarrow \rho(p_t - 1)(p_{t+1} - 1) \cdots (p_{u-1} - 1) / (2^{n_0} p_1^{n_1} p_2^{n_2} \cdots p_{t-1}^{n_{t-1}} p_t p_{t+1} \cdots p_{u-1})$.
 - 5.6 Return(ρ).
-

4.3 Probability of success ρ for $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves

Table 4 presents the probability of success of Algorithm 3 for $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves. This shows the probability of obtaining the scalar k using a single faulty point $\tilde{P} \in \widehat{E}(\mathbb{F}_{2^m})$ and specific values of parameter e . We notice that with the minimum amount of exhaustive search (i.e., $e = 0$) the values are close to $1/2$, especially for the Koblitz curve cases where the relation between the two smallest prime factors of $\#\widehat{E}(\mathbb{F}_{2^m})$ is greater (e.g., $p_1/2 \approx 10.8 \times 10^6$ for the example of the Koblitz curve over $\mathbb{F}_{2^{409}}$). Also for the Koblitz curve examples, it can be noticed that with $e = 2$ their probabilities are close to unity as shown in the fifth column of Table 4. In contrast, for the randomly chosen curves, similar values close to the unity are obtained with $e = 10$ as illustrated in the right-most column of this table.

Case	m	ρ				
		$e = 0$	$e = 1$	$e = 2$	$e = 5$	$e = 10$

	571	1	1	1

Table 5: Minimum value of parameter e for obtaining a probability ρ smaller than some given values for $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves

Table 5 shows the minimum value of parameter e for obtaining a probability ρ smaller than some specific values. From this table it can be noticed that for practical situations e could be quite small for an exhaustive search (e.g., say 14) and still have a reasonably high probability of success ρ (e.g., $\rho > \frac{999}{1000}$).

³The case of $m = 283$ for Koblitz curves is omitted for this and any subsequent table since there does not exist a cryptographically weaker group $\widehat{E}(\mathbb{F}_{2^m})$.

Cost of Algorithm 3. Most of the computational cost of Algorithm 3 is involved in phases 2 and 3, i.e., obtaining k partially using the Silver-Pohlig-Hellman algorithm (Algorithm 2) and the exhaustive search with verification process, respectively. The cost of both phases depends on the order of \widehat{P} , i.e., n , and the order $\#\widehat{E}(\mathbb{F}_{2^m})$. Let us consider the cost of each phase:

- *Silver-Pohlig-Hellman’s algorithm (phase 2 of Algorithm 3).* Step 1.3.2 of the Silver-Pohlig-Hellman algorithm (Algorithm 2), which is the only step in this algorithm with significant cost, needs to compute one EC discrete logarithm. This operation can be performed with a fast algorithm for ECDLP such as Pollard’s rho algorithm [18] with an expected number of point operations of about $3\sqrt{p_{t-1}}$, where p_{t-1} is the largest prime divisor of n . This running time can be further reduced using a parallelized version of the Pollard’s rho algorithm [25] to about $(\sqrt{\pi p_{t-1}/2})/M$ point operations, where M is the number of processors used for solving the ECDLP instance. Additionally, as shown by Gallant et al. [10] if a Koblitz curve over \mathbb{F}_{2^m} is utilized, then the parallelized version of the Pollard’s rho algorithm can take about $(\sqrt{\pi p_{t-1}/m})/(2M)$ point operations.
- *Exhaustive search and verification (phase 3 of Algorithm 3).* With $n = \text{ord}(\widehat{P})$ and $\#\widehat{E}(\mathbb{F}_{2^m})$, the exhaustive search space r is obtained using Equation (8) (see Step 9 of Algorithm 3). Thus, assuming $t \approx m$ the phase 3 of Algorithm 3 will require r scalar multiplications in the worst case which represents at most $(3mr)/2$ point operations if a binary method is utilized.

Example 3 Let us consider the cost of phases 2 and 3 of Algorithm 3 for $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curve *K-163*. For a single processor, the cost of phase 2 is of about $3\sqrt{p_4} \approx 2^{43.6}$ point operations, where p_4 is the largest prime factor of $\#\widehat{E}(\mathbb{F}_{2^m})$ (see Table 2). Now, assume that we have $M = 10,000$ computers for solving the instance of the ECDLP. In this case the expected number of point operations for each processor is approximately $(\sqrt{\pi p_4}/163)/20000 \approx 2^{24.9}$. For the phase 3 cost, from Tables 3 and 5 we can notice that with a probability greater than $\frac{999}{1000}$ the exhaustive search space will be less than 2^{10} , which implies a number of point operations $< 3(163)(2^{10})/2 \approx 2^{17.9}$.

5 Attack with unknown faulty base finite field pair \widetilde{P}

Fault model Let us assume that the adversary can inject a single bit-flip fault into the x -coordinate of the input point $P_i = (P_{i,x}, P_{i,y}) \in E(\mathbb{F}_{2^m})$ of a device computing the ECSM utilizing Algorithm 1 for some i . Suppose that the resulting finite field pair after the fault injection $\widetilde{P}_i = (\widetilde{P}_{i,x}, P_{i,y})$ is unknown. Also, consider that the fault location is at a random position of the x -coordinate. Consider that the result $\widetilde{Q}_i = k\widetilde{P}_i = (\widetilde{Q}_{i,x}, \widetilde{Q}_{i,y})$ is realized.

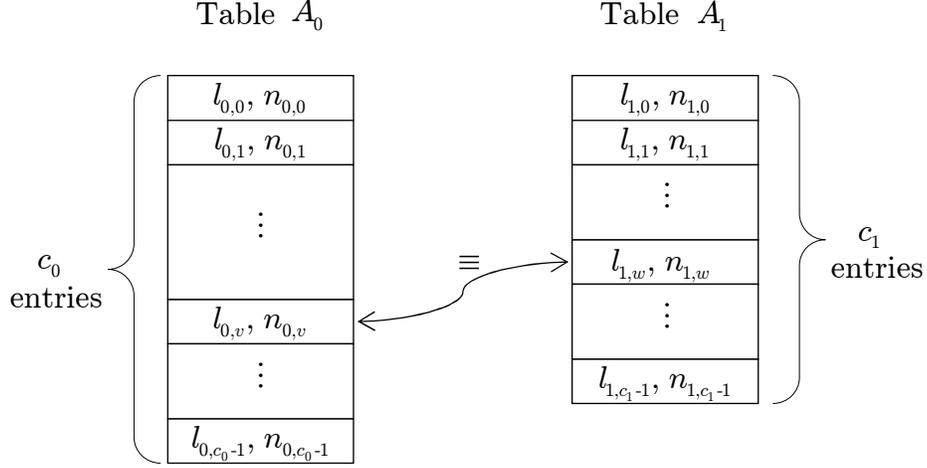

Figure 1: Tables A_0 and A_1 with the output of the Silver-Pohlig-Hellman algorithm for each $(R_{i,j}, \widehat{Q}_i, n_{i,j})$, where $i \in \{0, 1\}$, $j \in [0, c_i - 1]$, and $n_{i,j} = \text{ord}(R_{i,j})$

5.1 Attack description

Under this scenario the attacker might retrieve the secret scalar as follows. First, it is necessary to collect some faulty outputs of the form $\widetilde{Q}_i = k\widetilde{P}_i = (\widetilde{Q}_{i,x}, \widetilde{Q}_{i,y})$ for which there exists a point $\widehat{Q}_i \in \widehat{E}(\mathbb{F}_{2^m})$ such that $\widehat{Q}_i = (\widehat{Q}_{i,x}, \widehat{Q}_{i,y})$ for some $\widehat{Q}_{i,y} \in \mathbb{F}_{2^m}$. In fact, with two different points $\widehat{Q}_i \in \widehat{E}(\mathbb{F}_{2^m})$, where $i \in \{0, 1\}$, and some acceptable amount of exhaustive search it is possible to obtain k with a high probability.

Let \widehat{P}_i be a point in $\widehat{E}(\mathbb{F}_{2^m})$ with the same x -coordinate as $\widetilde{P}_i = (\widetilde{P}_{i,x}, P_{i,y})$, i.e., $\widehat{P}_i = (\widetilde{P}_{i,x}, \widehat{P}_{i,y}) \in \widehat{E}(\mathbb{F}_{2^m})$ for some $\widehat{P}_{i,y} \in \mathbb{F}_{2^m}$. Since \widetilde{P}_i (and consequently \widehat{P}_i) is unknown, we need to guess it among those finite field pairs that differ from each P_i in only one bit of their x -coordinate. Let c_i be the number of possible candidates for \widehat{P}_i , where $i \in \{0, 1\}$. Let $R_{i,j}$ be a candidate for \widehat{P}_i , where $i \in \{0, 1\}$ and $j \in [0, c_i - 1]$. Initially, by Lemma 1 we can expect that c_i is about $m/2$. However, this amount could be further reduced depending on the order of \widehat{Q}_i . This is possible because we know that $\text{ord}(\widehat{Q}_i) \leq \text{ord}(\widehat{P}_i)$, and more precisely $\text{ord}(\widehat{Q}_i) \mid \text{ord}(\widehat{P}_i)$. Let η_i be the reduction factor due to the latter condition such that $c_i \approx \eta_i \frac{m}{2}$.

After collecting the faulty outputs we can construct two tables A_i of c_i entries with the output of the Silver-Pohlig-Hellman algorithm for each $(R_{i,j}, \widehat{Q}_i, n_{i,j})$, where $i \in \{0, 1\}$, $j \in [0, c_i - 1]$, and $n_{i,j} = \text{ord}(R_{i,j})$. These tables are illustrated in Figure 1. Thus, having $l_{i,j} \bmod n_{i,j}$ in each entry of Tables A_0 and A_1 , we could distinguish those that are likely to be equivalent to either k or $\#\widehat{E}(\mathbb{F}_{2^m}) - k$. The idea is to search entry pairs v and w that satisfy either

$$l_{0,v} \equiv l_{1,w} \pmod{\text{gcd}(n_{0,v}, n_{1,w})} \quad \text{or} \quad (17)$$

$$l_{0,v} \equiv \#\widehat{E}(\mathbb{F}_{2^m}) - l_{1,w} \pmod{\gcd(n_{0,v}, n_{1,w})}. \quad (18)$$

In practical situations where $m \geq 163$ it is more likely to have a unique candidate pair that satisfies either (17) or (18). The main reason is because it is expected that $n_{i,j} \gg c_i$ for $i \in \{0, 1\}$ and $j \in [0, c_i - 1]$. Nevertheless, even if there is not a unique candidate pair it is possible to verify which one is equivalent to k or $\#\widehat{E}(\mathbb{F}_{2^m}) - k$ after performing an exhaustive search similarly to the attack presented in the previous subsection. The complete attack procedure is presented in Algorithm 5. Let e be a parameter such that 2^e is the maximum acceptable amount of exhaustive search per candidate pair found in Step 5 of Algorithm 5. Also, let us define σ as the probability of success for retrieving the scalar k using Algorithm 5.

Algorithm 5. Invalid-curve attack with unknown faulty base point \widetilde{P}

Input: E defined over \mathbb{F}_{2^m} , access to Algorithm 1, base point $P_i = (P_{i,x}, P_{i,y}) \in E(\mathbb{F}_{2^m})$ with $i \in \{0, 1\}$, the order $\#\widehat{E}(\mathbb{F}_{2^m})$, a parameter for acceptable amount of exhaustive search e .

Output: Scalar k with a probability of σ

Phase 1: Collect faulty outputs

1. $i \leftarrow 0$.
2. While ($i < 2$) do
 - 2.1 Inject a fault in $P_i = (P_{i,x}, P_{i,y})$ for obtaining $\widetilde{P}_i = (\widetilde{P}_{i,x}, P_{i,y})$.
 - 2.2 Compute $\widetilde{Q}_i = k\widetilde{P}_i = (\widetilde{Q}_{i,x}, \widetilde{Q}_{i,y})$ using Algorithm 1.
 - 2.3 $T_1 \leftarrow \widetilde{Q}_{i,x} + b/\widetilde{Q}_{i,x}^2 + \widehat{a}$.
 - 2.4 If ($\text{Tr}(T_1) = 0$) then
 - 2.4.1 $\widehat{Q}_{i,x} \leftarrow \widetilde{Q}_{i,x}$, $\widehat{Q}_{i,y} \leftarrow \widetilde{Q}_{i,x} \cdot \text{Ht}(T_1)$, $i \leftarrow i + 1$.

Phase 2: Construct tables

3. For $i = 0$ to 1 do
4. $T_2 \leftarrow 1$.
 - 4.1 For $j = 0$ to $m - 1$ do
 - 4.1.1 $R_x \leftarrow P_{i,x} + T_2$.
 - 4.1.2 $T_3 \leftarrow R_x + b/R_x^2 + \widehat{a}$.
 - 4.1.3 If ($\text{Tr}(T_3) = 0$) then
 - (a) $R_y \leftarrow R_x \cdot \text{Ht}(T_3)$.
 - (b) Obtain $n = \text{ord}(R)$.

(c) If $(\text{ord}(\widehat{Q}_i)|n)$ then

(i) Utilize Algorithm 2 with (R, \widehat{Q}_i, n) to obtain $l \bmod n$.

(ii) Store (l, n) in Table A_i .

4.1.4 $T_2 = T_2 \ll 1$.

Phase 3: Searching for candidate pairs

5. For some entries v and w in tables Tables A_0 and A_1 , respectively, search for candidate pairs that satisfy $l_v \equiv l_w \pmod{\text{gcd}(n_v, n_w)}$ or $l_v \equiv \#\widehat{E}(\mathbb{F}_{2^m}) - l_w \pmod{\text{gcd}(n_v, n_w)}$.

6. For the candidate pairs where $l_v \equiv \#\widehat{E}(\mathbb{F}_{2^m}) - l_w \pmod{\text{gcd}(n_v, n_w)}$ set $l_w \leftarrow \#\widehat{E}(\mathbb{F}_{2^m}) - l_w \pmod{n_w}$ in Table A_1 .

Phase 4: Exhaustive search and verification

7. For each candidate pair do

7.1 Solve the system of congruences $l \equiv l_v \pmod{n_v}$ and $l \equiv l_w \pmod{n_w}$.

7.2 $n \leftarrow \text{lcm}(n_v, n_w)$.

7.3 Find the smallest value of r for $\text{lcm}(n, r) = \#\widehat{E}(\mathbb{F}_{2^m})$.

7.4 If $(r = 1)$ then

7.4.1 Compute $R = l\widetilde{P}$ using Algorithm 1.

7.4.2 If $(R = \widetilde{Q})$ then return(l);

7.4.3 Else if $(R = -\widetilde{Q})$ then return($\#\widehat{E}(\mathbb{F}_{2^m}) - l$).

7.5 Else if $(r \leq 2^e)$ then

7.5.1 $k' \leftarrow 0$.

7.5.2 While $(k' < r)$ do

(a) Solve the system of congruences $k'' \equiv k' \pmod{r}$ and $k'' \equiv l \pmod{n}$.

(b) Compute $R = k''\widetilde{P}$ using Algorithm 1.

(c) If $(R = \widetilde{Q})$ then return(k'');

(d) Else if $(R = -\widetilde{Q})$ then return($\#\widehat{E}(\mathbb{F}_{2^m}) - k''$);

(e) Else $k' \leftarrow k' + 1$.

8. Return("failure").

Table 6: Minimum, maximum and average number of entries of Tables A_i for $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves

Number of entries of Tables A_0 and A_1 . Let $\#\widehat{E}(\mathbb{F}_{2^m}) = 2^{e_0} p_1^{e_1} p_2^{e_2} \cdots p_{u-1}^{e_{u-1}}$ be the prime factorization of $\#\widehat{E}(\mathbb{F}_{2^m})$. As stated before, the number of entries of Table A_i , c_i , depends on the reduction factor η_i . The latter in turn depends on the order of \widehat{Q}_i and the order of the candidate points for \widehat{P}_i , $R_{i,j}$, where $i \in \{0, 1\}$ and $j \in [0, c_i - 1]$. Assuming that the points $R_{i,j}$ are taken randomly from the group $\widehat{E}(\mathbb{F}_{2^m})$, it can be shown that η_i depending on $\text{ord}(\widehat{Q}_i)$ has the following bounds

$$\eta_{\max} \leq \eta_i \leq 1,$$

where $\eta_{\max} = \frac{1}{2} \prod_{j=1}^{u-1} (1 - \frac{1}{p_j})$. The lower bound of the above expression correspond for the case when $\text{ord}(\widehat{Q}_i) = \#\widehat{E}(\mathbb{F}_{2^m})$. In this case the reduction factor is maximum (i.e., η_{\max}), and consequently the number of entries of Table A_i is minimum (i.e., $c_{\min} \approx \frac{\eta_{\max}m}{2}$). On the other hand, theoretically the upper bound of η_i holds only when $\text{ord}(\widehat{Q}_i)$ is the point of order two $(0, \sqrt{b})$. However, for the cases where $p_1 \gg 2$ (e.g., $\widehat{E}(\mathbb{F}_{2^m})$ for the Koblitz curves of Table 2) if $\text{ord}(\widehat{Q}_i) = \#\widehat{E}(\mathbb{F}_{2^m})/2^{e_0}$, then the reduction factor is close to unity. For these cases the number of entries of Table A_i is maximum (i.e., $c_{\max} \approx \frac{m}{2}$). In Table 6 the values of η_{\max} , c_{\min} , and c_{\max} are given for each $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves. Also, this table shows the average cases for η_i and c_i (i.e., $\bar{\eta}$ and \bar{c} , respectively).

Algorithm 5 needs to compute in total $c_0 + c_1$ EC discrete logarithms using the Silver-Pohlig-Hellman algorithm. This number is fixed since the search for candidate pairs and the exhaustive search phases are performed after the tables's construction. If we merge these three phases, a speedup on average can be achieved. Let us describe two approaches one could take to combine these phases:

1. We can first completely construct Table A_0 . Then, each time an entry of Table A_1 is obtained we can verify whether this entry satisfies the congruence in (17) or (18) with any entry of A_0 . For each candidate pair found (if any) we proceed with the

exhaustive search and verification process. If the verification fails, then we continue to obtain the next entry of Table A_1 and repeat the process until the scalar is obtained. Even when using this approach the number of EC discrete logarithms in the worst case is the same as that using Algorithm 5 (i.e., $c_0 + c_1$), on average it is roughly $c_0 + \frac{1}{2}c_1$.

2. Another approach is to construct Tables A_0 and A_1 in alternate way. Each time an entry in A_i is obtained, we can search Table $A_{\bar{i}}$ for candidate pairs that satisfy either Congruence (17) or (18) for $i \in \{0, 1\}$. For each candidate pair found (if any) we proceed with the exhaustive search and verification process. This process is repeated until a candidate pair passes the verification process, i.e., the scalar is found. Let Tables A_0 and A_1 be of the same size, i.e., $c_0 = c_1$. For this case the average number of EC discrete logarithms is $\approx \frac{4}{3}c_0$. In Appendix A we show how the latter value is obtained. This appendix also includes the case where $c_0 \neq c_1$.

5.2 Obtaining the probability of success σ

The probability of success σ of Algorithm 5 depends on parameter e and the order of both \widehat{P}_0 and \widehat{P}_1 . Consider that the latter two points are taken randomly from the group $\widehat{E}(\mathbb{F}_{2^m})$. For each trio $(\widehat{P}_i, \widehat{Q}_i, n_i)$, the Silver-Pohlig-Hellman algorithm provides $l_i \bmod n_i$, where $i \in \{0, 1\}$ and $n_i = \text{ord}(\widehat{P}_i)$. Utilizing these values, a system of congruences is solved and a solution $\bmod n$ is obtained, where $n = \text{lcm}(n_0, n_1)$ (see Step 7.2). This “combination” of modulus n_i might reduce the exhaustive search space in comparison with the individual case of n_0 or n_1 . This observation permits us to obtain a relation between the probabilities of success ρ and σ for Algorithms 3 and 5, respectively. In this case ρ is the probability that from an individual pair (l_i, n_i) , $i = 0$ or 1 , we could obtain the scalar using exhaustive search for a given value of e . Then we can express σ as follows:

$$\sigma = 2\rho - \rho^2 + \lambda. \tag{19}$$

The first two terms represent the probability that for a given e we could obtain the scalar from at least one of the two pairs. The third term, λ , is the probability that the “combination” does succeed in obtaining the scalar with exhaustive search when neither pair individually does so for a given value of e . Equation (19) gives an explicit lower bound for σ , i.e., $\sigma \geq 2\rho - \rho^2$. In fact, for the cases of $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves we notice that $\sigma \approx 2\rho - \rho^2$ for $e \geq 2$.

For obtaining a more precise value of σ one can check, from all the possible order values of two points (i.e., \widehat{P}_0 and \widehat{P}_1), which ones provide sufficient scalar information for obtaining the rest using exhaustive search for a given parameter e . Additionally we need to consider the probability of occurrence of every point order combination. The complete procedure is put together in Algorithm 6.

Algorithm 6. Probability of success σ for Algorithm 5

Input: The order $\#\widehat{E}(\mathbb{F}_{2^m}) = 2^{n_0} p_1^{n_1} \cdots p_{u-1}^{n_{u-1}}$, a parameter for acceptable amount of exhaustive search e , where $e \geq 0$.

Output: Probability of success σ .

1. $\sigma = 0$
 2. For $J_{u-1} = 0$ to n_{u-1} do
 - For $J_{u-2} = 0$ to n_{u-2} do
 - \vdots
 - For $J_0 = 0$ to n_0 do
 - $D \leftarrow 2^{J_0} p_1^{J_1} \cdots p_{u-1}^{J_{u-1}}$
 - $N \leftarrow \phi(D)$
 - For $j_{u-1} = 0$ to n_{u-1} do
 - For $j_{u-2} = 0$ to n_{u-2} do
 - \vdots
 - For $j_0 = 0$ to n_0 do
 - $d \leftarrow 2^{j_0} p_1^{j_1} \cdots p_{u-1}^{j_{u-1}}$
 - $n \leftarrow \mathbf{1cm}(D, d)$
 - Find the smallest value of r for $\mathbf{1cm}(n, r) = \#\widehat{E}(\mathbb{F}_{2^m})$.
 - If $(r \leq 2^e)$ then
 - $\sigma \leftarrow \sigma + N \cdot \phi(d)$.
 3. $\sigma = \sigma / (\#\widehat{E}(\mathbb{F}_{2^m}))^2$
 4. Return(σ).

5.3 Probability of success σ for $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves

Table 7 presents the probability of success of Algorithm 5 for $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves. This shows the probability of obtaining the scalar k for specific values of parameter e . These values were obtained using Algorithm 6. We notice that the probability of success is better in comparison with the basic attack. In fact, for $e \geq 2$ the relation between the probability of success of both attacks is $\sigma \approx 2\rho - \rho^2$. In Table 8, we list the minimum value of parameter e for obtaining a probability σ smaller than some specific values. This table shows that even with small values of e (e.g., say 14) the probability of success is quite high (e.g., $\sigma > \frac{999,999}{1,000,000}$).

Case	m	σ				
		$e = 0$	$e = 1$	$e = 2$	$e = 5$	$e = 10$

Table 7: Probability of success σ of obtaining k with Algorithm 5 for $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves for a given parameter e

Cost of Algorithm 5. The most significant computational cost of Algorithm 5 is involved in phases 2 and 4, i.e., construction of tables and the exhaustive search with verification process, respectively. Let us consider the cost of each phase:

- *Construction of tables (phase 2 of Algorithm 5).* Comparing with the basic attack presented in the previous subsection (Algorithm 3), Algorithm 5 needs to perform $c_0 + c_1$ instances of the Silver-Pohlig-Hellman algorithm (Algorithm 2) instead of one, where c_i is the size of Table A_i for $i \in \{0, 1\}$. Similar to the cost of phase 2 of Algorithm 3, the cost to construct the tables with a single processor is about $3(c_0 + c_1)\sqrt{p_{t-1}}$ point operations, where p_{t-1} is the largest prime divisor of $\#\widehat{E}(\mathbb{F}_{2^m})$. If M processors are used, then about $(c_0 + c_1)\sqrt{\pi p_{t-1}/2}/M$ point operations are required. If a Koblitz curve over \mathbb{F}_{2^m} is utilized, then this cost can be reduced to about $(c_0 + c_1)(\sqrt{\pi p_{t-1}/m})/(2M)$ point operations. These costs clearly depends directly on values of c_i which depends on the order of \widehat{Q}_i and the order of the candidate points for \widehat{P}_i . As discussed earlier, the bounds for c_i are approximately $\frac{\eta_{\max} m}{2} \leq c_i \leq \frac{m}{2}$, where η_{\max} is the maximum reduction factor which depends on $\#\widehat{E}(\mathbb{F}_{2^m})$.
- *Exhaustive search and verification (phase 4 of Algorithm 5).* In phase 3 of Algorithm 5 using Tables A_0 and A_1 , a search for candidate pairs that satisfy either (17) or (18) is performed. As discussed earlier, for today's applications where $m \geq 163$ it is expected to have a unique candidate pair. In this way, in phase 4 an exhaustive search is performed in order to obtain the full value of the scalar. Here, the exhaustive search space r is obtained in Steps 7.2 and 7.3. Thus, assuming $t \approx m$ the phase 4 of Algorithm 5 will require r scalar multiplications in the worst case which represents at most $(3mr)/2$ point operations if a binary method is utilized.

Case	m	Parameter e (in bits)		
		$\sigma < 1 - \frac{1}{100}$	$\sigma < 1 - \frac{1}{1000}$	$\sigma < 1 - \frac{1}{1 \times 10^6}$
Randomly chosen curves	163	2	5	10
	233	5	5	12
	283	3	9	14
	409	2	6	12
	571	3	5	5
Koblitz curves	163	2	2	10
	233	1	1	1
	409	1	1	1
	571	1	1	1

Table 8: Minimum value of parameter e for obtaining a probability σ smaller than some given values for $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves

Example 4 *Let us consider the cost of phases 2 and 4 of Algorithm 5 for $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curve K-163. Let us use the minimum and maximum values of c_i from Table 6 to give an interval for each cost. For a single processor, the cost of phase 2 is approximately in the interval $[6c_{\min}\sqrt{p_4}, 6c_{\max}\sqrt{p_4}] \approx [2^{49.9}, 2^{50.9}]$ point operations, where p_4 is the largest prime factor of $\#\widehat{E}(\mathbb{F}_{2^m})$ (see Table 2). Now, assume that we have $M = 10,000$ computers for solving the instances of the ECDLP. In this case the expected number of point operations for each processor is approximately in the interval $[\frac{c_{\min}(\sqrt{\pi p_4/163})}{10000}, \frac{c_{\max}(\sqrt{\pi p_4/163})}{10000}] \approx [2^{31.2}, 2^{32.2}]$. For the phase 4 cost, from Tables 3 and 5 we can notice that with a probability greater than $\frac{999}{1000}$ the exhaustive search space will be $r \leq 4$. Here the cost of phase 4 is negligible.*

6 Countermeasures

The attacks presented in the previous section only need one or two faulty outputs to break the given instance of ECSM with a high probability of success. Hence, this may constitute a threat to cryptosystems using the Montgomery ladder ECSM for elliptic curves over the binary field. Therefore, some countermeasures are needed. In the following, we will describe possible protections against the attacks presented in this report.

Group formulas change. A possible countermeasure is to use alternative group formulas that include both elliptic curve parameters a and b . However, such formulas are likely to require more computations and hence cause a degradation in terms of performance. Additionally, if this approach is the only protection used, no errors due to faults are detected and this might constitute a risk for other attacks such as the DFA attack presented by Biehl

et al. [2].

Curve selection. The attacks presented in this report assume that $\widehat{E}(\mathbb{F}_{2^m})$ is a cryptographically weaker group where the ECDLP could be solved in a reasonable period of time for a given $E(\mathbb{F}_{2^m})$. However, this assumption is not true if both $\#E(\mathbb{F}_{2^m})$ and $\#\widehat{E}(\mathbb{F}_{2^m})$ are almost prime. From the NIST-recommended curves, the only curve that satisfies this condition is referred to as K-283. Although, this curve selection criteria is an effective countermeasure against the fault-based attacks presented in this report, it might be too restrictive from the practical point of view. Moreover, the following two countermeasures represent a possible solution without limiting the use of particular group $E(\mathbb{F}_{2^m})$ even when the order of $\widehat{E}(\mathbb{F}_{2^m})$ is not an almost prime number.

Point verification (PV). It is important to verify that the input point is in $E(\mathbb{F}_{2^m})$. In the case that this checking could be bypassed, it is more important to verify whether or not the output is on the original elliptic curve. This countermeasure not only prevents from the attacks presented in this report, but also others such as those described by Biehl et al. [2], Ciet and Joye [4], and Antipa et al. [1]. It is important to note that this verification needs to be implemented in a secure environment. Otherwise the attacker might bypass this protection and carry out an invalid-curve attack such as one of those described earlier in this report.

Coherency check (CC). In addition to PV that could be applied to any ECSM algorithm, the Montgomery ladder ECSM algorithm permits us to have another way to detect errors in scalar multiplication using coherency check (CC). We can use the fact that the temporary pair (Q_0, Q_1) is of the form $(l \cdot P, (l + 1)P)$ for some integer l at any value of i during the loop of Montgomery's algorithm. Since the difference between Q_1 and Q_0 should be P at any iteration, one can check this during and after the ECSM operation. Note that if the attacker is able to modify the input point P in the way described in Algorithms 3 and 5, the operation $Q_1 - Q_0$ needs to be implemented using group formulas that include both curve parameters, a and b , or at least parameter a for avoiding that this checking operation is performed in $\widehat{E}(\mathbb{F}_{2^m})$. This approach for error detection is presented in more detail in [6].

7 Conclusion

In this report we have presented two invalid-curve attacks that apply to the Montgomery ladder ECSM algorithms proposed by López and Dahab [13]. These attacks exploit the fact that parameter a is not used in the group formulas for these particular algorithms. In this way, if $\widehat{E}(\mathbb{F}_{2^m})$ is a weaker group with the same parameters than the original group $E(\mathbb{F}_{2^m})$ except for parameter a and we are able to inject a fault in the input point as described in Algorithms 3 and 5, then we would retrieve the scalar k with a high probability of success. For the purpose of the NIST-recommended curves, we have shown that there exists a weaker

group for nine of the ten cases that include the randomly chosen and Koblitz curves. The only exception is the curve K-283 for which $\#E(\mathbb{F}_{2^m})$ and $\#\widehat{E}(\mathbb{F}_{2^m})$ are almost prime. Also, we have obtained the theoretical probability of success for each of the presented attacks. Additionally, we have determined numerical values of the probabilities of success for $\widehat{E}(\mathbb{F}_{2^m})$ from the NIST-recommended curves. And finally, we have presented some countermeasures to prevent the attack described in this report.

A Average Number of EC Discrete Logarithms for Algorithm 5

In this appendix we include the computations of the average number of EC discrete logarithms for Algorithm 5 using the second improved approach described on page 24. As assumed in Subsection 5, the fault location is at a random position of the x -coordinate of the base point P . This assumption implies that the value of $k \bmod n_i$ is at a random position in Tables A_i , where $n_i = \text{ord}(\widehat{P}_i)$ and $i \in \{0, 1\}$. Let us define the random variable w as the number of entries needed for having $k \bmod n_i$ in both tables. The order of the possible values of w is shown in Figure 2 for the case $c_0 < c_1$.

Case: $c_0 = c_1$. In this case the accumulative probability distribution $F(w)$ for some given values is as follows:

$$\begin{array}{ll}
 F(1) = 0 & F(2) = 1/c_0^2 \\
 F(3) = 2/c_0^2 & F(4) = 4/c_0^2 \\
 F(5) = 6/c_0^2 & F(6) = 9/c_0^2 \\
 F(7) = 12/c_0^2 & F(8) = 16/c_0^2 \\
 \vdots & \vdots \\
 F(2c_0 - 1) = (c_0 - 1)/c_0 & F(2c_0) = 1
 \end{array}$$

We can write $F(w)$ as

$$F(w) = \begin{cases} (w^2 - 1)/(4c_0^2) & w \text{ odd, and } 1 \leq w \leq 2c_0 - 1, \\ w^2/(4c_0^2) & w \text{ even, and } 2 \leq w \leq 2c_0. \end{cases}$$

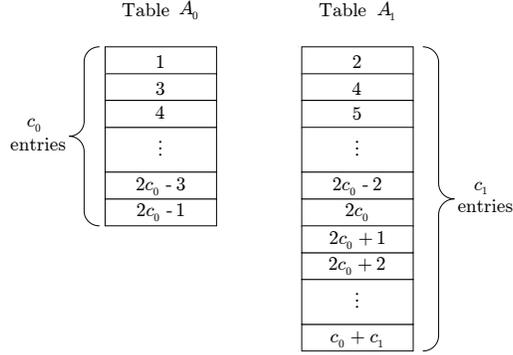

Figure 2: Values of the random variable w according to entries of Tables A_0 and A_1 considering $c_0 < c_1$

Then the probability distribution $f(w) = F(w) - F(w - 1)$ is

$$f(w) = \begin{cases} (w - 1)/(2c_0^2) & w \text{ odd, and } 1 \leq w \leq 2c_0 - 1, \\ w/(2c_0^2) & w \text{ even, and } 2 \leq w \leq 2c_0. \end{cases}$$

The mean μ can be expressed by

$$\mu = \sum_{w=1}^{2c_0} w f(w).$$

After performing a change of variables (i.e., $y = \frac{w-1}{2}$ and $y = \frac{w}{2}$ for the odd and even number cases, respectively) μ can be re-written as

$$\mu = \sum_{y=0}^{c_0-1} \frac{y(2y+1)}{c_0^2} + \sum_{y=1}^{c_0} \frac{2y^2}{c_0^2} = \frac{8c_0^2 + 3c_0 + 1}{6c_0} \approx \frac{4}{3}c_0 \quad (\text{for } c_0 \gg 1). \quad (20)$$

Case: $c_0 < c_1$. Similar to the previous case we can write $F(w)$ for some given values as follows

$$\begin{array}{ll}
F(1) = 0 & F(2) = 1/(c_0c_1) \\
F(3) = 2/(c_0c_1) & F(4) = 4/(c_0c_1) \\
F(5) = 6/(c_0c_1) & F(6) = 9/(c_0c_1) \\
\vdots & \vdots \\
F(2c_0 - 1) = (c_0 - 1)/c_1 & F(2c_0) = c_0/c_1 \\
F(2c_0 + 1) = (c_0 + 1)/c_1 & F(2c_0 + 2) = (c_0 + 2)/c_1 \\
\vdots & \vdots \\
F(c_0 + c_1 - 1) = (c_1 - 1)/c_1 & F(c_0 + c_1) = 1
\end{array}$$

We express $F(w)$ as

$$F(x) = \begin{cases} (x^2 - 1)/(4c_0c_1) & x \text{ odd, and } 1 \leq x \leq 2c_0 - 1, \\ x^2/(4c_0c_1) & x \text{ even, and } 2 \leq x \leq 2c_0, \\ (x - c_0)/c_1 & 2c_0 + 1 \leq x \leq c_0 + c_1. \end{cases}$$

For this case the probability distribution $f(x)$ is

$$f(x) = \begin{cases} (x - 1)/(2c_0c_1) & x \text{ odd, and } 1 \leq x \leq 2c_0 - 1, \\ x/(2c_0c_1) & x \text{ even, and } 2 \leq x \leq 2c_0, \\ 1/c_1 & 2c_0 + 1 \leq x \leq c_0 + c_1. \end{cases}$$

We can obtain the mean μ as follows

$$\mu = \sum_{x=1}^{c_0+c_1} xf(x)$$

After performing a change of variables (i.e., $y = \frac{x-1}{2}$ and $y = \frac{x}{2}$ for the odd and even number cases, respectively, where $1 \leq x \leq 2c_0$) μ can be expressed as

$$\begin{aligned}
\mu &= \sum_{y=0}^{c_0-1} \frac{y(2y+1)}{c_0c_1} + \sum_{y=1}^{c_0} \frac{2y^2}{c_0c_1} + \sum_{x=2c_0+1}^{c_0+c_1} \frac{x}{c_1}, \\
\mu &= \frac{3c_1^2 - c_0^2 + 6c_0c_1 + 3c_1 + 1}{6c_1}. \tag{21}
\end{aligned}$$

Case: $c_0 > c_1$. This case is vary similar to the previous case. In fact, from Equation (21) we can perform the changes of variables $c_0 \leftarrow c_1$ and $c_1 \leftarrow c_0$ to obtain the mean for this case:

$$\mu = \frac{3c_0^2 - c_1^2 + 6c_0c_1 + 3c_0 + 1}{6c_0}. \quad (22)$$
